Some authors claim that the global financial crisis can be considered an aftermath of conventional finance, given that it doesn't follow the ethical principles of Islam (Chirinko et al. 2018). Among these, the prohibition of *riba* inhibits the extractive source of earning money, while it helps in the circulation of capital in productive enterprise, leading to higher levels of capital formation and production in the real sector of the economy and higher levels of employment. Islamic financial institutions help drive savings into investments, converting money capital into productive capital. Islamic ethics limit the consumer choice from immoral activities, lavish consumption, and wastage of resources. Furthermore, Islamic ethics compels firms to avoid hoarding essential items, distorting price mechanisms, and engaging in unethical marketing and promotion of consumerism. Islamic redistribution institutions redistribute wealth from the rich to the poor. For instance, *Zakat* discourages hoarding of wealth and ensures circulation of capital, while *Waqf* ensures the decentralized provision of public goods and social safety nets in an Islamic economy. Lastly, the Islamic inheritance laws ensure wealth redistribution across generations in every family.

Islamic economics can welcome micro foundations as an illustration of human behavior in the economic sphere of life. However, the systems, institutions, and policymaking that Islamic economics offer cannot consider human behavior as a rule, only as a guide. Islam is a comprehensive doctrine that can provide the basis for a dependable social contract and institutions that attend to issues of welfare and equity. The ideals of Islamic finance and Islam economics are profit sharing and profit-and-loss sharing. People can earn and possess money, but they are called to manage it as God's steward or vice-regent, *khalifah* (El-Ashker and Wilson 2006). People

cannot be exploited or cheated by interest payments that increase income inequality.

In this regard, the Islamic Development Bank (Iqbal 1997; Iqbal et al. 1998; Khan 2010) describes the lending requirements by stating that the most influential feature of Islamic banking – its promotion of risk sharing between the provider of funds (investor) and both the financial intermediary (the bank) and the user of funds (the entrepreneur). In principle, in conventional banking, this risk is supported by the entrepreneur. This requirement is met by *Sharia*'a-compliant financial products (Visser 2012).

The injunctions derived from the aim to comply with the precepts of the *Sharia* allow some authors to argue that managers at Islamic banks are more attentive to avoiding unethical business than commercial banks. The *Shari'ah* supervisory boards in Islamic banks affect managerial behavior and mitigate agency problems (Lewis 2011). Correspondingly, a link between corporate ethics and management behavior through *Shari'ah* can be established (Quttainah 2012; Quttainah and Almutairi 2017).

Several authors have pointed out that pro-social behavior (i.e., altruism, philanthropy, volunteering, and social activism) does not arise purely from a personal and self-centric choice framework (Bruni and Uelmen 2006; Lubich 2007; Gold 2010; Zsolnai 2011). In religious societies, religious teachings provide the impetus to pro-social acts (Qutait 2018) and religious values drive preferences that affect both non-economic and economic choices (Rice 1999; Wilson 2002).

The practical nature of the Islamic faith gives followers a code of life that guides all aspects of their human existence (Mir 2010). Ethical principles find a primary source in the *Qur'an* and *Sunnah* (the prophetic tradition) that provide clear and rigid caveats for leading a virtuous Islamic life (Beekun and Badawi 2005).

The key axioms that rule the ethical philosophy of Islam comprise unity, equilibrium, free will, responsibility, and benevolence (Beekun 1997). Benevolence (*ehsan*) sets the standard for ethical conduct (Iqbal and Cam 2018) and influences both personal and commercial dealings in several ways that reflect goodwill, generosity, and a duty

to help others in need. Accordingly, authors have pointed out that the importance of Islamic ethics concerns responsible conduct and the creation of societal good and benefit for all, rather than pursuing personal self-interest, thus distinguishing it from free-market capitalism (Ali and Al-Aslie 2015).

Islamic ethics recommends a strong social responsibility in commerce and profit moderation, instead of profit maximization (Iqbal and Cam 2018). The emphasis on societal welfare reinforces the importance of corporate social responsibility (Solomon 2003) and has several common points with a sustainability-driven approach and the orientation toward creating long-term value.

Drawing from these lines of thought that emphasize the role of cultural factors, social norms, and spiritual stimuli on economic behavior, the Divine Economics framework considers religion or religious activities as an object of choice in a rational framework and studies it in the labor-leisure choice, as well as in the intertemporal consumption choice (Qutait 2018). Divine Economics – introduced as an attempt to endogenize the religious factors in the mainstream economic framework, starting with a seminal contribution published in a South Asia prominent academic journal (Hamdani et al. 2002) – has been defined as a framework for the study of economics and religion while considering both perspectives (Hamdani and Ahmad 2002). The motivation for developing such a framework comes from the view that most of the work done by Muslim economists is normative, legalistic, and idealistic (Hamdani 2002), while very few studies have addressed the positive aspects of economic behavior in religious and non-religious households. Divine Economics framework has some points of similarities with Islamic economics and can contribute to economics literature, which has yet to make effective interactions and cross-communication with most of the mainstream schools of economics (Azid 2010). The points of differences come from the fact that the Divine Economics framework wants to remain universal in its applicability, thus leading to less interest from the Muslim economists who want to build the Islamic economics literature by keeping

the Islamic normative values at the core of their analysis.

Key Issues

A core point within the aims and claims of Islamic finance is tied to its capability to yield a feasible and credible *Sharia*-compliant replacement for conventional finance.

Compared with conventional finance, both (potential) strong and weak points have been discussed (Visser 2009; Ahmmed et al. 2015; El-Gamal 2006). Among the former are lower risk of financial ruin due to the absence of interest rate risk, protection against financial crises, increase of participation in the official financial system, and a limitation of speculative activities (Visser 2012). Among the latter one can enumerate: a shift of risks from shareholders to depositors; higher transaction costs, because Islamic contract law requires a distinct contract for each transaction (Van Duyn 2010); principal-agent problems, because of the higher moral-hazard risk.

In addition, conventional insurance is considered unacceptable because it is closely linked to investments in interest-earning. On the other hand, the Islamic solution – *takaful*, a mutual fund based on the contribution of participants – rests on brotherhood. However, the ideals of brotherhood are not easy to apply and may take the form of *zakat* (Islamic charity) and *qard hasan* (beneficence) loans that play a marginal role among Islamic bank's activities.

Finally, legal uncertainties should be mentioned. First, Islamic finance agreements are often presided over by English law and if the underlying assets are situated in Middle Eastern countries, the enforceability of the contracts may be problematic. Second, Islamic contracts are affected by a *Sharia* risk in the absence of uniform standards to assess which financial tools are *Sharia*-compliant. Despite the efforts of standard-setting bodies, such as the Accounting and Auditing Organization for Islamic Financial Institutions. The standards have not been yet

universally accepted and are only obligatory in a few countries.

Summary

Islamic finance can be considered a beneficial addendum to conventional financial products. The ethical principles fundamental to Islamic finance (in particular, the ban on interest) can attract non-Muslims and affect conventional finance, even if for others they only offer a chance to vary their portfolios or profit.

However, a thriving Islamic finance sector may help to tackle the interconnectedness between financial institutions and their business models “vices” (i.e., the enormous scale of activities on derivative markets and their reliance on short-term borrowings). The conventional banking industry could learn from the Islamic financial sector and overcome the dependency on short-term borrowing (Chapra 2007). Moreover, the Divine Economics framework can contribute to creating a bridge between Islamic economics and mainstream economics by providing a factual analysis of “how religious households behave” without highlighting the Islamic normative teachings (Qutait 2018). In this regard, the discussion on what can encourage responsible economic and financial behaviors can benefit from empirical studies focused on how faithful economic agents use resources and public goods and how preferences are amenable in the light of different beliefs and worldviews.

Islamic Governance

Vedran Jakupović

Faculty of Health Studies, University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Definition

Governance is relationship between government and governed people, and following the same principle corporate governance is relationship between the corporation and constituents. Islamic governance follows Islamic rules and modus operandi in the process of governance. Puts the stress on Islamic values, spiritual and tangible needs of the community, relationship between corporate goals and benefits of all stakeholders (customers, suppliers, employees, competitors). Islamic values are fuel for the company governed in Islamic way and should be the basis for creating corporate goals, codes of conduct, codes of ethics, etc. Islamic governance deals with property rights, contracting and finding the way to create and implement an adequate incentive system. Islamic law and morality are the framework in which Islamic corporation should be created. At the same time there is a challenge for the entrepreneurs living in non-Muslim countries with no Islamic law and financial system. But the award for striving to achieve virtue of deeds is higher.

Introduction

Islamic governance is mostly connected with Islamic banking, Islamic finance, and with performing business in Islamic states. But truly, Islamic governance is connected with running business all over the world, and it is even more important, not only in Islamic banking and

Islamic finance but in areas of management, marketing, business ethics, Human Resource Management (HRM), legal issues, etc.

The word governance comes from the Greek word “kubernaein” and the Latin verb “gubernare” which means “to steer.”

By definition, governance is the relationship between the governor and the governed. This applies to the state, but it can also apply to companies in terms of the power held by people in management and their relationship with subordinates. Conceptually, the leadership of the state and the company are similar, and both the company and the state choose the way of governance.

Islamic Governance

According to Lewis there are three types of governance:

1. Legal, which answers the question “by whom,” that is, how the company was created and who is responsible for the company’s activities. This concept can be problematic in the Islamic understanding of the company management.
2. Economic, which answers the question “for whom,” whereby the company was created either to maximize profits or take care of stakeholders.
3. Accounting, which answers the question “with what resources” the company is capacitated.

In line with these types, Lewis made the difference between three possible approaches to corporate governance (Lewis 2005).

1. Managed corporation model
2. Socially responsive corporation
3. Islamic governed corporation

The managed corporation model strives to maximize profits, and the value of shares. Decisions are made by the CEO and top management, while the finances are managed by shareholders and investors. In contrast, in socially responsive corporation processes are led by executive and supervisory boards, decisions are made for

stakeholders, which indicates that this approach is based on stakeholder theory. The resources used to perform the work are at the level of corporate responsibility toward society and the community, not only toward shareholders. This is called “the triple bottom line” agenda, which has an economic, social, and environmental dimension, and which takes care of sustainability and corporate social responsibility.

In an Islamic governed corporation, decisions (by whom) are made by the shura, a group whose mechanism of action is based on consultation and agreement. If it is a question of “for whom the corporation works” and “for whom it does the work,” the answer is the community, where the base of action is represented by hisba, the supervision that implements the agenda of “commanding right and forbidding wrong.” And ultimately the answer to the question with what resources goes through the shariah, the religious audit. This is especially related to the institution of zakat, a special type of mandatory tax on money or harvest (Azid et al. 2007).

Shura

The shura assumes expert consultation before making a decision. It can be similar to the stakeholder theory in which boards (executive and supervisory) or committees play an important role. Counseling has deep roots in Islam and remains a positive practice today.

Hisbah and Muhtasib (Supervision)

Ibn Teymiyye said that all services in Islam should command right and forbid wrong. *Hisbah* is the service that controls the correctness of business, and muhtasib is the person who performs this task. *Hisbah* originates from the Prophet Muhammad (peace be upon him), who personally controlled the quality of the grain in the market and when he found that the wet grain was hidden under the dry one, he said to the merchant: “Those who cheat us are not from us.” Many papers have been published on this topic, which indicates its

importance. Muhtasibs checked industry, professional services, product standardization, associations, bad practices, as well as supply and demand. In addition to this segment, social behavior, religious obligations, and civic activities of people are also controlled.

Shariah

As stated earlier the behavior of a company in Islam should not differ from that of an individual Muslim as a person. Considering that the company is not a living being, it is the actions of the manager that will give the direction and pattern of behavior. The sources of *shariah* are Quran, hadith, *ijma* – consensus of ulama and *kiyyas* – analogy. In business, it serves to prevent and react to all possible management anomalies.

Islamic governance has its deep roots in Quran and hadith. These sources regulate all aspects of life and business as well. Business must be inspired and guided by *tawhid* (oneness of God), *ihsan* (kindness), *tawakkul* (fear of Allah and awareness of Allah's constant presence), along with constant awareness of what is permitted and what is prohibited, that is, interest (*Riba*). The mode of action must be based on justice, kindness, honesty, patience, the desire to spend money for the benefit of the community. At the same time company should avoid prohibited acts and traits such as tyranny (*zulum*), greed, accumulation of wealth, and unnecessary extravagance.

Some countries allow the full application of Sharia law, while in most others this type of norm is not entirely possible. Regardless of the state regulation, an Islamic company must adhere to the above-mentioned principles, rules, and prohibitions. That means that the way a company operates in Islam should not be different from the way an individual, a believer, operates.

The Islamic system is based on rules that "lead to rewards if followed or punishment if not followed." Therefore, accepting the rules puts a person in a position to behave correctly and thereby contribute to community and society. In the legal sphere, all details are implemented

through Islamic law. This refers to contracts, the way the company is organized, the issue of ownership, payments, etc.

The company's organizational system must comply with applicable laws. If there are any deviations that affect the proper operation of the company, the system is obliged to remove them. The goal of this approach is to protect social justice. A direct relation to work is mentioned in many places in the Quran; the relations of the employees toward the company they work for, the trust shown to them *amanah* (legacy), and their acceptance of the institute of contract. It is stressed that the employee must not knowingly harm the company, but also that the company must do everything to protect the rights of its workers.

Property in Islam

Basis for the further talk is the property issue in Islam. Society in Islam exists for the benefit of the individuals in it. The company operates through state and other organizations.

Ownership in Islam can be absolute or real and delegated or restricted due to the time limit of ownership. The owner of everything in the heavens and on earth is Allah, which assumes that man cannot be the true owner, but only the one who manages what is entrusted to him as a trustee or custodian. However, an individual is formally the owner, and he is subject to numerous restrictions, whereby he must not cheat, exaggerate, skim the scale, or hide the goods until their value increases due to some accident. Individuals have obligations toward themselves, their neighbors, and society. Islamic economics insists that the purpose and goal of the market is cooperation, compassion, solidarity, and doing good. One of the Qur'anic obligations is the fulfillment of contracts. The ownership is determined by the contract, it can be inherited, can be transferred to another person, and in case of sale, the contract should contain an offer and acceptance of the offer. If the terms of the contract are inappropriate, the contract cannot be considered valid (Iqbal and Mirakhor 2004).

The Relationship Between the Company and Corporate Social Responsibility

Although Friedman emphasized that profit maximization is actually the company's social responsibility in an Islamic company, the company's goal is to serve society. If the company operates in this way, it fulfills its obligation to God. This can be observed at the micro and macro level, activities in the community and globally. Special importance in Islam is given to common property and within that to the institution of *waqf* or public good (Islahi 2015). The two basic axioms of Islamic economics, *Rububiya* and *Tazkiya*, insist that the company's operations are in harmony with society and its natural environment. *Rububiya* refers to strengthening, growing, and sustaining on the path of God's perfection, while the *tazkiya* is dedicated to the growth and purification of attitudes and relationships. This shows how important is the relationship between society and the company that operates in that society (Ahmad 1994).

Challenges of Islamic Governance

The main issue is the conductivity of Islamic law, if it even exists in the country where the company operates. This concept must be followed regardless of the existence of Islamic law. The concept of doing business according to Islamic principles can be implemented all over the world, if the owner or the board is determined to implement the goals of Islamic business.

Consultation is necessary, but a careful selection of the experts who will be consulted is necessary too. It is obligatory to include both internal and external influential members.

Many scholars have pointed out, applying Islamic principles requires deep insight of the social, cultural, and political environments.

Beekun makes the distinction between *shari* principles and *tabi* principles. *Shari* principles are derived from revelation. Their objectives are to distinguish between what is permissible and what is forbidden and to create a just economic system. The *tabi* principles are the natural principles that

determine efficiency, competence, and performance (Beekun and Badawi 2005).

Interest-based loans, a major concern with the way the economy is structured is that it is simply not sustainable. Sustainability has become a strategic imperative for many organizations.

Defensive routines is a polite way of saying that most people in the organization hide facts to avoid embarrassment. This means that inaccurate communication is the norm inside the organization, and this influences the strategic management process as facts, opinions, and analyzes are presented in such a way as to protect people from embarrassment and harassment.

Conflicts of interest arise whenever a reward system has been poorly designed. If there is a conflict of interest, we cannot have regular communication and relationship within the company. This can cause mistrust, disrespect, and additional problems (Fontaine and Ahmad 2013).

Summary

Islamic governance is a model of company management with respect for Islamic principles and values. It is closely and directly related to stakeholder theory, but it is not completely identical to it. In Islamic management, the focus is on the correct interpretation of ownership rights, compliance with signed contracts and agreements, creation of the best way to compensate employees, and, ultimately, on quality relations between the company and all stakeholders. There is a special focus on the benefits for the community and society, whereby voluntary participation in social processes is emphasized, apart from the mandatory payment to the state in the form of taxes or *zakat*. Islamic leadership starts with the consultation of experts in a certain field (*shura*), then a concept is created and the goals and action strategies are defined. The control is carried out in the *hisbah* process. The competent controllers – *muhtasib* – include all aspects of business and behavior within the framework of Islamic rules. Ultimately, the company's resources are allocated through the rules set by the *shariah* to the places that are permitted, in the manner that is permitted and

avoiding prohibitions. The entire business process is marked with Islamic ethics, kind attitude, fairness, and desire for the welfare of all people who have contact with the company, whether they are product buyers, service users, owners or co-owners, workers, managers, or residents in the area where the company operates. Islamic governance is easier to practice in the countries of the Islamic world where Islamic law rules, and business is also adapted to the rules required by Islamic teachings. This particularly applies to Islamic finance and banking. At the same time, it is necessary to find ways and make additional efforts to facilitate Islamic governance as a positive practice throughout the world.

Islamic Stakeholder Theory

Vedran Jakupović

Faculty of Health Studies, University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Definition

The importance of stakeholders in business was pointed out in the 1980s by the issuing of Freeman's Stakeholder Theory. It emphasizes all of those who are influenced and affected in any way by the company's activities. Over the years, a number of authors have contributed toward the improvement and advancement of this theory. At the same time, among Islamic business scholars and practitioners, the proximity of the Islamic way of doing business to this theory, and especially to the association toward the community and society as a whole was made clear again. This is how the Islamic stakeholder theory was created. It unified the practice of Islam, the obligations of Islamic business management, put stakeholders in their place, marked the absolute and relative right of ownership, and encouraged the importance of ethical behavior in business. Stakeholders (owners, management, and workers) in Islam have strict instructions on how to chart the direction, what they can and cannot do, what to produce, what to trade, what to invest in. Both the relation of the worker to the job and the company, and of the employer to the workers were explained. Their attitude toward the community, customers, and service users as well as their attitude toward the competition is clarified. Islamic rules are clear. They are easier to implement in Islamic countries where Islamic law prevails. Simultaneously, they provide the framework for doing business throughout the world.

Body of Text

Stakeholder theory is the concept which has been introduced in the mid-1980s by Freeman, and developed by various authors such as Donaldson,

Islamic Social Systems

- [Islamic Finance](#)

Cornell, Shapiro, Baum, Blair, Preston, Simmons, Kakabadse, and others (Kakabadse et al. 2005).

Stakeholder theory focuses on what an organization owes to the various constituencies that it is dependent on for its success. According to Freeman, stakeholder theory focuses on a core issue: on whose behalf and at whose expense is the business being run.

Stakeholder theory stands as an opposition to the traditional theory of profit maximization, which only cares about shareholders, and as such enters the sphere of the needs of all stakeholders, the sphere of business ethics, morality, corporate social responsibility, etc. In its foundation, the company chooses the governance model by which it will be run.

The traditional approach in economics and legal science is based on the agency relationship between investors and managers and focuses only on protecting the interests of investors and shareholders. According to this model, shareholders should have control, managers have a strict obligation to serve only the interests of investors, and that the business goal is profit maximization. This model is labeled as an agency model in contrast to the stewardship model, which focuses on stewards who work in the general interest, not only in the interest of shareholders.

The company is an integrated part of society and as such has certain moral and ethical obligations. In the creation and formulation of the company's goals, in addition to the business goals, these factors must also be included. The source of the ethics by which the corporation is guided is found in the basis of the corporate governance model, whereby the western, more precisely the Anglo-Saxon, model is predominantly secular and has no basis in religious values. Throughout history, the separation between the state and the church has been built, ever since the Roman era when the saying was created; Render to Caesar the things that are Caesar's, and to God the things that are God's (Mark 12:17 (KJV)). Due to this fact, from the beginning of the development of corporations, there was a separation from religious, moral and ethical principles, and rules created by man were accepted.

In contrast to this attitude toward religion in the Anglo-Saxon world, in the Islamic world the basis of all activity is the observance of religious rules. The rights of individuals, societies, states, the legal system, the question of ownership, the way of organization, and of running a corporation in Islam are viewed through the prism of Islamic belief, as well as the responsibilities and obligations that arise from it. Shariah (Islamic law) provides a broad framework for understanding, recognizing, protecting, and respecting every living being, and then also the community, society, and state. State governance in Islam is closely related to company governance. Violation of these rights is marked as *zulum* – tyranny – and is subject to severe punishment. It was even stated that a righteous non-Muslim ruler is more acceptable than a non-righteous Muslim ruler (one who does evil).

Understanding normative Islam's approach to business ethics may help the world at large grasp the mindset of Muslim businesspersons (Beekun and Badawi 2005).

From the above we can conclude that the stakeholder theory is much closer to the Islamic model and as such will be the subject of this chapter.

In Islam, a stakeholder is anyone whose property rights are at risk due to the willing or unwilling activities of the company.

It is important to emphasize that the Islamic concept of life is present on the entire planet, and it is not important in which state the principle is implemented, but how correctly it is implemented. The state is obliged to provide a framework for sustainable business according to the principles of Islam. According to the Islamicity index, this framework includes economic, legal and governance, human and political rights, and international relations components. The index shows that the best Islamic framework was achieved by New Zealand, Canada, and the countries of Northern Europe. The first Muslim country is Malaysia in the 39th place, followed by the UAE in the 43rd (Islicity index 2023), which confirms that the framework for the Islamic stakeholder theory must have a wider context, and not only the geographical determinant of the Islamic world.

The question of ownership in Islam starts from the fact that Allah (SWT) is the owner of everything in the heavens and the earth, and therefore man can only be his caliph, governor, administrator on earth. This is close to the concept of stewardship that we had the opportunity to see in stakeholder theory. According to some scholars, a person has the right to take only what is permitted to him and only as much as he needs from this property of Allah.

Islam recognizes two ways of acquiring wealth. Through work and through inheritance or a certain type of transfer, agreement, donation, etc. Gambling, bribing, forgery, cheating, stealing, coercion, etc., are not permitted. Artificial creation of scarcity and profiteering in difficult circumstances, such as various crisis situations, are also not allowed. Interest is strictly prohibited.

Conceptually, an Islamic company should focus on three things:

- That the production and distribution of something that is prohibited (haram) is equal to zero
- That the production and distribution of goods that meet people's ordinary needs is much higher than luxury goods
- That profit maximization is moderate, striving to make money, but avoiding greed

Islam adopts a stakeholder perspective that is somewhere between Freeman's approach and Goodpaster's. Whereas Freeman considers the claims of all stakeholders (defined as employees, management, owners/financiers, customers, suppliers, and the community) as equally valid, Islam recognizes the fact that the owners/financiers of a firm have the right to make a profit, but not at the expense of the claims of various other stakeholders. The firm does have a multi-fiduciary responsibility but in contrast to what Freeman (1984) proposes, Islam does not view all stakeholders as having equal claims (Beekun and Badawi 2005).

Attitude Toward Owners (Shareholders)

The issue of ownership has already been mentioned in the text, but it is important to clarify in

detail the Islamic concept of corporate ownership. So Allah is the absolute owner of everything in the heavens and on earth. People are caliphs (trustees, custodians), they have been entrusted with the management of a certain segment, be it the state or a corporation (Quran 57.7). Accordingly, we distinguish three types of relative ownership, individual, social, and state ownership. Individuals are obliged to fulfill obligations toward society and the state, and this especially applies to *zakat*, a tax that an individual is obliged to pay into the state treasury or a special treasury if the state is not in charge of collecting. If the person who is perceived as the owner complies with all Sharia rules and obligations toward society and the state, his property is protected and inviolable. If the general rules of the Islamic concept are not followed, ownership becomes questionable. However, in any case, the rights of shareholders or owners must go through legal procedures and must not be influenced by lump sum assessments.

The contract in Islam is present from the very roots. Allah made a contract with man by the very fact that man accepted to be the caliph on Earth. Just as important as a written contract is an oral one, and of particular importance is the intention – *niyyet* – to do a good or bad deed. In the Koran it is said "O you who believe, fulfill the contract" (Quran 5.1) (Iqbal and Mirakhor 2004).

Attitude Toward Workers

Islam values knowledge and skills, allows hierarchy and accepts differences in abilities, and therefore different valuation of workers. At the same time, hereditary and preferential rights in employment are not allowed in any form (Quran 46.19). Discrimination of any kind is not allowed. No preference was given to an Arab over a non-Arab or a non-Arab over an Arab. Special attention was given to the relationship between the boss (shareholder) and subordinates or servants. The hadiths of Prophet Muhammad indicate this issue. A special reward was promised to the worker who takes care of the employer's

property (Islahi 2015). Ibn Taymiyah suggests that an employer is under obligation to pay a fair remuneration to his employees. Therefore, the employer is required to take special care in relation to the employee. The worker should be paid for his work before his “sweat dries,” so there is no delay in payment or debt to the worker. The hadith says that all people are dependent on Allah, and the best among them are those who are benevolent toward the people who are in their possession (dependents) and those who distribute wealth justly.

This is in line with the opinions that the understanding and acceptance of the meaning and purpose of the business by employees, and thus creating a sense of belonging to the company, is essential for its good functioning. If the employee connects his identity with the company’s identity, work efficiency becomes higher than in the case of mere financial compensation (Ahmad 1979). Employers must take care of the working conditions, physical and health conditions of their employees, but also of other members of the community.

Work in Islam is perceived as *ibadah* (worshiping God) and as such must be mutually respected. Work is an obligation for a healthy Muslim and should be used to its full capacity.

Attitude Toward Users of Products and Services

The company’s activities directed toward users of products and services must be in accordance with Islamic postulates. This especially refers to an ethical, sincere, honest relationship with customers. The customer information segment is very important, in which the company is obliged to inform the customer in detail and accurately about the product or service, type, price, origin, distribution. Trade in which there is no benefit, trade in worthless goods, trade in illegal, *haram* products (alcohol, pork, etc.) is prohibited, and it is important to emphasize again the strict prohibition of interest, causing damage, unfavorable deadlines, harassment, and corruption (Azid et al. 2007).

Attitude Toward Stakeholders Participating in Production

Islam does not consider the maximum use of all the company’s resources a problem if it does not conflict with the interest of the community. One of the goals of the company must be the creation of a healthy working environment, along with the improvement of society and the community. If the company’s setting is aligned with these postulates, fewer strikes and dissatisfaction among employees can be expected.

Attitude Toward Society (Corporate Social Responsibility)

The goal of a company in Islam is not only the maximization of profit but also the maximization of social charity. The goal is profit, but also social well-being. In order to reach this goal, we must insist on moral and ethical business and values. This means that an entrepreneur must strive to satisfy both material and spiritual needs. The desire for profit must not lead an entrepreneur into the framework of illegal, prohibited activities.

When it comes to society, the desire to maximize profits can be achieved by raising prices, which negatively affects society, or by reducing costs, especially wages, which negatively affects workers and morale within the company. Maximizing profit at the expense of social welfare is not acceptable in Islam. The company should focus on achieving goals, but it is primarily a service to society and as such should be in harmony with the environment in terms of economic and ecological sustainability, while at the same time giving its share in charitable activities, mandatory or voluntary.

Ethics in Islam

Sources of ethics in Islam are the same as sources of *shariat* – Quran, Hadith (messenger Muhammed’s saying) as primary sources as well as *Ijma* (consensus of scholars) and analogy *Qiyas*.

According to Beekun, criteria of relevance for stakeholders are justice and balance, trust and benevolence (Beekun and Badawi 2005).

“The criterion of justice is described by two words in the Qur’an: ‘adl and qist;’ ‘*adl* means “equity, balance.” Muslims are encouraged to behave justly towards all. At the same time, the term ‘adl also applies to the concept of balance and equilibrium. It means doing things in a proportionate manner, avoiding extremes. Justice is also described in the Qur’an by another important word: Qist. It means “share, portion, measure, allotment, [or] amount.” The word qist means to give everyone and everything their proper due.

The second criterion of Islamic ethics relates to the concept of *amanah* or trust. Man is God’s trustee on earth and as such must bear responsibility for his actions. The wealth and other resources that mankind has access to are not his, but have been loaned to him by God as tools to fulfill the responsibilities of the trusteeship.

The third criterion of Islamic ethics is benevolence or excellence. Benevolence (*ihsaan*) or kindness to others is defined as “an act which benefits persons other than those from whom the act proceeds without any obligation.” At its core, the word *Ihsaan* is derived from the Arabic root h-s-n which means “suitable,” “beautiful,” “proper,” or “and this concept is the core of Islamic ethics because it focuses on behavior for the love of the God.”

Conclusion

Islam is a way of life, not just a religion. As a result, business in Islam cannot be separated from other aspects of life. Islamic stakeholder approach shows where is the place of specific stakeholders in proportion to their importance. The responsibility of each stakeholder is to follow the Islamic rules, shariah law, act as a trustee or guardian on the Earth, and at the same time think about community and society. This theory is useful in Islamic states, but indeed it is the framework which has a wider context, and not only the geographical determinant of the Islamic world.

[The sustainability concept in Islam](#)

Description of Islamic Sustainability

Economic inequality, unconscious abuse of natural resources, and unethical practices in business life have brought sustainability to the agenda. Sustainable development draws global attention

to the negative effects and deficiencies of the current economic system, environmental and social problems such as the climate crisis, pollution, overpopulation, and inequality. This awareness has led to concerns and conscious awareness among people from different cultures and societies. Considering sustainability from the perspective of the religion of Islam, it expresses a traditional, natural, and actually not a new approach. Islamic philosophy is derived from two main sources, namely, “Al-Quran” (the central religious text) and “Sunnah” (words and teachings of Prophet Muhammad). Based on these, “Allah” (the God) is the absolute owner and as a sign of his greatness, he is responsible for creating all creatures in the universe in harmony whereas mankind is a “trustee” of the world. The Earth is encompassed by several resources that are enough and sufficient for all human beings if they are managed and consumed wisely (Sarkawi, Abdullah, and Dali, 2016). Since both the religion of Islam and the concept of sustainability advocate the idea that the universe should be preserved to be able to pass on to future generations and its resources should be protected as well, the concept of Islamic sustainability, which examines these two concepts together in an integrated way instead of isolating them, has started to be discussed in the literature.

Sustainable Development from an Islamic Perspective

The concept of sustainability, which was coined by the Brundtland Commission in 1987, was defined as “*development that meets the needs of the present without compromising the ability of future generations to meet their needs*” (WCED, 1987, p. 43). Hasan (2006) expresses that the Brundtland Commission’s view on sustainable development is in parallel with the Islamic values and objectives. Initially, the definition of the concept and its development has a global character and is effective for all in the world. Similarly, Islam is also a universal religion that “addresses the entire mankind not the believers alone.” In addition, the ultimate aim of the Islam focuses

on the human well-being through “safeguarding faith, human self, intellect, posterity and wealth.” Thus, “wisdom, mercy, and justice” are required to achieve this objective (Hasan, 2006, p.8). Based on this, Islamic sustainability considers the Muslim belief and the behaviors brought by this belief as a rule and guide that can affect the social, environmental, and economic dimensions of sustainability. There are numerous principles and values related to the economic, social, and environmental dimensions of sustainability in Islam. Moreover, Ahmadi (2016, p.7) indicates that Islam provides new perspectives to the notion of sustainable development in regard to understanding and clarifying the antecedents of the existing environmental, economic, and social matters that arise from overpopulation, poverty, human security, human and labor rights, depletion of natural resources, environmental contamination, and climate change.

Sustainable development with an Islamic approach shows a perspective beyond the material benefits provided by the environment and natural resources. Human beings are a part of nature, but among all other creatures, they are superior with their mental capabilities, and their reliance will be questioned on the “Day of Resurrection” as a provision of the fundamental rules of Islam. All resources are blessings given by the “Creator” (the God, Allah) and require the awareness that these blessings are temporary. This necessity can be demonstrated with an approach that values nature by avoiding waste and gives importance to spiritual development as well as material development. The economic, social, and environmental problems created by the practices of the current system’s political, economic, and social institutions began to manifest themselves in all areas of life. As a result of economic development, the rights and natural resources of local and Indigenous people can be restricted in line with the needs determined by developed countries. Its structure covering a very wide range of sustainability necessitates its development as a model. Thus, Islamic view provides a new perspective to achieve a balance between economy, society, and environment and enables to protect spiritual or nonmaterial needs of people through promoting

spirituality, justice, and protection of the environment together with protecting material needs required for economic performance (Hasan, 2006).

The most basic teaching in Islamic culture is to realize consumption, which is seen as a necessity beyond wealth and luxury life, and therefore to protect resources. If these resources are not protected, from the Islamic point of view, “fasad” (ecological deterioration, moral corruption, and disturbance of peace) will bring social exclusion along with it. Concerns about the social dimension, equality, social justice, “shura” (public participation), and the living conditions of future generations, which are an important dimension of sustainability, constitute the most important building blocks of Islamic philosophy. Taking both the material and spiritual aspects of life together as a whole is an expression of devotion to Allah, and this can be achieved in the best way with the most correct use of the resources in the world (Ahmadi, 2016).

Environmental Dimension of Sustainability

From an Islamic point of view, the universe, the earth, sun, moon, all animals, and plants, in its simplest sense everything one can imagine in the environment, have been created by Allah with a particular purpose. Thus, all natural resources are recognized as the gift of Allah so that appreciation to the environment can be seen as a worship to Allah. In addition, it is believed that arbitrary and selfish use of natural resources should be prevented. To maximize benefitting from the resources for all, people must seek ways to protect the environment on the planet in accordance with the provisions of Al-Quran and Sunnah. Thus, the balance and harmony of the universe are significant necessities to maintain and preserve the earth and the environment (Ahmadi, 2016). According to Al-Quran “respecting the law of nature and all its components is an obligation of every Muslim” (Matali, 2012, p. 35). This view is in accordance with the environmental sustainability goals of meeting the needs of today without endangering the resources required by the future generations (Nouh, 2012). In line with the Brundtland Commission’s perspective, Al-Quran emphasizes the

concept of needs, instead of wants, and advises to avoid damaging renewable and nonrenewable resources including water, soil, forests, animals, etc. Accordingly, each individual in the world has the right to benefit equally from the resources offered by the environment and should consider the potential needs of future generations when exercising this right (Ahmadi, 2016).

Economic Dimension of Sustainability

Islamic economic perspective is related to social issues, and thus they are based on sharing and optimizing wealth distribution. Islam promotes development and growth socially and economically regarding socioeconomic improvement via “waqaf” (endowment) and “zakat” (alms) provisions (Sarkawi et al., 2016). As a rule of thumb, transactions are forbidden as the gain of somebody may result in a loss for another, so a transaction should be socially optimal, and mutual approval is not enough for a permissible transaction (Ahmadi, 2016). Economic activities can only be realized if there are sufficient resources. Thus, from the Islamic perspective, the economy is dependent on the environment which is believed as Allah’s creation and humankind should have the responsibility in managing the economic and environmental resources in regard to satisfy both economic (material) and spiritual (nonmaterial) needs of the people (Sarkawi et al., 2016).

Social Dimension of Sustainability

As a part of the role of humankind in the functioning of the universe, adding value to life with his spiritual values, helping others, and providing scientific development for future generations refer to the social lifestyle of humans from the Islamic point of view. It is one of the most important Islamic teachings to stay away from waste and overly focused consumption while maintaining this lifestyle.

Ethical practices in the social dimension of sustainability are also accepted as the most important feature that organizes social life in the religion of Islam. It is a concept that expresses the most efficient use of existing resources, the equitable and fair distribution of these resources, and the

support of groups in need through alms and emphasizes the issue of social justice. The religion of Islam, which accepts the differences between individuals, states that wealth may not be equally distributed in a society, but this situation can be balanced with help and benevolence. Through alms and philanthropy, social justice can be effectively achieved. The Islamic perspective, which emphasizes the importance of giving, has made Muslims a part of an effective social apparatus with various teachings that will ensure social justice (Ahmadi, 2016).

Spiritual Dimension of Sustainability

As Islam propagates the idea that human beings are responsive to manage the resources they need in the universe rationally with their mental capabilities and should not cause harm to any other creature while doing so, it provides an ethical code to people to live in harmony. Although Islam has the moral agenda necessary to ensure sustainable development, efforts and practices should be comprehensively addressed to mitigate the economic and environmental crises encountered, and this perspective should be included in Islamic sustainability (Ansari, 1994; Niaz, 2001). Odeh (2009), who argues that sustainable development cannot be realized by excluding the spiritual aspect of people from an Islamic perspective, emphasizes that the essence and mission of humanity should be preserved in this process. Shaharir (2012) argues that sustainability has been narrowly defined so far and remarks the need of the inclusion of the spiritual and cultural dimensions of the human being in the content of the sustainability definitions. Addressing sustainability with an Islamic perspective contributes to filling this gap and deficiency.

Summary

Islam deals with various aspects of sustainable development, and values of the Islamic perspective are compatible with the notion of sustainable development. Thus, the responsibility of human beings to the natural and social environment and using the resources in a sustainable manner are the

fundamental features recognized and widely accepted. From the Islamic perspective, sustainability can be defined by Shaharir (2012) as follows:

“...a state of being achieving a wusta (moderate, middle way, balanced and just) level of physical, social, political, economic, science-knowledge, cultural and religio-spiritual needs of the present man without sacrificing the all relevant resources and all beings created by the God so that future generations will be able to enjoy at least the same level of happiness in this world and hereafter as the present generation” (Shaharir, 2012, p.95).

Islamic sustainability presents significant features. First, social and economic sustainability are interrelated, and they are both part of the environment. Thus, the coordination, balance, and interaction between people and the environment is necessary for the maintenance of the system. Second, nature, which is recognized as a test for human beings, who are the members of nature, will perform their social and economic tasks, and will be questioned on the Day of Resurrection, has been created in its natural order, in perfect balance. Third, biodiversity which is promoted by sustainable development guidelines has intrinsic and environmental meanings and values for human beings not only material resources but also spiritual existence. Under these circumstances, it is clear that there is a close relationship between Islam and sustainability (Sarkawi et al. 2016). Although not everyone in the world believes in Islam, Islam is a “universal religion” and is for everyone, just as the concept of sustainability is a global concept developed for the whole world.

Definition

The ISO 14000 standards series has been introduced in 1996 by the ISO Technical Committee ISO/TC 207 “Environmental management.” The ISO 14000 refers to a series of international environmental management system standards that can be implemented by all organizations (regardless of their size, activity, or sector) that tend to manage environmental responsibilities (ISO 2019). The most popular standard from the ISO 14000 standards series is ISO 14001 – according to “the ISO Survey of Certifications to Management System Standards” – there are “about 300.000 organizations, in over 170 countries – certified to ISO 14001” (ISO 2019). ISO 14001 specifies the requirements for all organizations that want to establish an effective environmental management system (ISO 2019). According to ISO (2015b) – ISO 14001 requires that all environmental aspects related to environmental performance are considered, such as – “air pollution, water and sewage issues, waste management, soil contamination, climate change mitigation and adaptation, and resource use and efficiency.” ISO 14001:2015 has been revised to address several aspects of the environmental management system, such as – encouraging leadership and commitment to enhance environmental performance, and introducing different environmental management aspects into the organizational strategy (ISO 2015b).

History

In 1992, the British Standards Institute (BSI) developed the BS 7750, the first environmental management system standard, and in 1996, ISO/TC 207 introduced the ISO 14000. The most popular standard from this series is ISO 14001:2015, and it was created as a result of growing needs to address sustainable development. According to ISO (2015a) – in recent years, a variety of actions have been taken to allow easier integration of ISO 14001:2015 with other management system standards, especially ISO 9001:2015, as both standards have the same structure (ISO 2015a). One of the most successful

actions refers to the development of a certain common standard ISO 19011:2018 – “Guidelines for auditing management systems” (ISO 2015a). The other standards from ISO 14000 standards series address aspects, such as – environmental performance, life cycle assessment, eco-labeling, greenhouse gas emissions, etc. (ISO 2019).

Benefits of Adopting ISO 14001

There are several benefits of adopting ISO 14001 that have been repeatedly stressed out in the current state of research – “environmental performance,” “efficiency,” and “profitability” (Tari et al. 2012). Other benefits of adopting ISO 14001 refer to the enhanced satisfaction of customers and stakeholders, enhanced global competitiveness, quality of goods and services, and sales (Tari et al. 2012). Similarly, enhanced global competitiveness, efficiency, and environmental performance are found to be most considered in the current state of research (Heras-Saizarbitoria et al. 2011). Accordingly, there is a belief that special attention shall be paid to “the management attitude towards the environment” (Heras-Saizarbitoria et al. 2011).

According to ISO (2015b) – users of ISO 14001:2015 also reported the following benefits:

- Ensure “compliance with current and future statutory and regulatory requirements”.
- Encourage the engagement of the top management, managers, and employees.
- Strengthen the organization’s brand and image “through strategic communication”.
- Enable the achievement of strategic organizational goals, objectives, and targets.
- Enhance global competitiveness, “through enhanced efficiency and reduced costs”.
- Enhance the environmental performance of all the stakeholders and interested parties.

PDCA (Plan-Do-Check-Act) Cycle

In the context of the ISO 14000 – Planning stands for establishing goals of the environmental

management system, all the resources needed for its implementation as well as all of the risks and opportunities for improvement (ISO 2015c). Doing refers to the implementation of all the planned environmental actions (ISO 2015c). Checking means monitoring and measuring (if applicable) results of processes and activities and reporting about all achieved outcomes (ISO 2015c). Acting means performing such actions to enhance organizational performance (ISO 2015c). Figure showing the structure of ISO 14001:2015 in relation to the PDCA cycle can be found at the ISO platform (see ISO 2020).

The classification of the core standards of ISO 14000 series in relation to the PDCA cycle (adapted and updated from ISO (2009)) is given in Table 1.

Besides all of the aforementioned published standards on environmental management, several standards are currently under development, such as:

- **ISO/WD 14002–2** – “Environmental management systems – Guidelines for using ISO 14001 to address environmental aspects and conditions within an environmental topic area – Part 1: Water”.
- **ISO/DIS 14009** – “Environmental management systems – Guidelines for incorporating material circulation in design and development”.
- **ISO/AWI 14015** – “Environmental management – Environmental due diligence assessment”.
- **ISO/AWI 14017** – “Environmental management – Requirements with guidance for verification and validation of water statements”.
- **ISO/WD 14020** – “Environmental labels and declarations – General principles”.
- **ISO 14021:2016 / DAMD 1** – “Environmental labels and declarations – Self-declared environmental claims (Type II environmental labeling) – Amendment 1: Carbon footprint, carbon-neutral”.
- **ISO/WD TS 14029** – “Mutual recognition agreements between Type III environmental declaration (EPD) program operators – Principles and procedures”.

Sustainable Development Goals (SDGs)

According to ISO (2019), ISO 14001:2015 contributes to the following SDGs:

- SDGs [1] – No Poverty.
- SDGs [2] – Zero Hunger.
- SDGs [3] – Good Health and Well-Being.
- SDGs [4] – Quality Education.
- SDGs [6] – Clean Water and Sanitation.
- SDGs [7] – Affordable and Clean Energy.
- SDGs [8] – Decent Work and Economic Growth.
- SDGs [9] – Industry, Innovation, and Infrastructure.
- SDGs [12] – Responsible Consumption and Production.
- SDGs [13] – Climate Action.
- SDGs [14] – Life Below Water.
- SDGs [15] – Life on Land.

Given that “accredited certification to ISO 14001:2015 is not a requirement” – “organizations can reap benefits from using the standard without going through the accredited certification” (ISO 2015b). The successful implementation of the environmental management system shall drive SDGs, add value, and enhance the environmental performance of most organizations (ISO 2015c). By addressing different aspects of the environmental management system and by setting out environmental goals, objectives, and targets, contemporary organizations shall be able to address sustainability objectives, thus achieving sustained success (ISO 2015c).

Summary

ISO 14000 refers to a set of international environmental management system standards that can be implemented by all organizations that tend to manage environmental responsibilities. The most popular standard from the ISO 14000 series is ISO 14001:2015 – and it was created as a result of growing needs to address sustainable

development. ISO 14001:2015 specifies the requirements for all organizations that tend to establish an environmental management system, thus addressing all environmental aspects related to their environmental performance. Other standards from the ISO 14000 series address different environmental aspects, such as – environmental performance, life cycle assessment, eco-labeling, or greenhouse gas emissions. The successful implementation of the environmental management system shall drive SDGs, add value, and enhance overall environmental performance, thus achieving sustained success.

[Environmental management system requirements](#); [Standard for environmental management system](#)

Definition

ISO 14001:2015 is an international standard for an environmental management system (EMS). It belongs to the group of management system standards published by the International Organization for Standardization (ISO). The ISO 14001 standard contains a set of requirements for establishing environmental policy, identifying and managing environmental aspects and impacts, planning measurable environmental goals, and implementing programs to achieve these goals. It includes guidelines for monitoring, preventive and corrective actions, as well as review by the top management. The standard promotes preventive approach to the protection of the environment and can contribute to sustainability of an organization. The standard can be a subject of certification by the external authorized institution. The certificate is usually issued for a specified period of time and confirmed by external audits carried out by this organization.

Management System Standards

The ISO 14001:2015 standard belongs to the family of management system standards. These include, for example, the ISO 9001:2015 quality management standard or ISO 45001:2018 the occupational health and safety management system standard.

Norms and standards are most often associated with the type of regulation that imposes specific requirements, for example, for measurable parameters that a standardized product must achieve or achievements that can be completed by the operating system. In addition, we associate such regulations with the obligation to comply with them. The standards that are management system standards do not match this picture. Not only that they are not mandatory, but they also regulate something that – it seems – to normalize is extremely difficult. This is true for the ISO 14001 standard and other management system standards. “In other words, they are not performance standards measuring the quality of a firm’s products or services or a firm’s environmental results; rather, they are standards setting out the need to systematize and formalize a large number of corporate processes within a set of procedures, and to document such implementation” (Tari et al. 2012, p. 298).

Namely, the standard sets out the requirements for an environmental management system. Organizations that want to implement, maintain, and improve an environmental management system and want to assure stakeholders that such a system has been successfully implemented and is functioning may or may not decide to meet the requirements proposed in these standards. Since they are voluntary, it should be assumed that there are motives other than legal coercion, which cause that a certain group of enterprises and other types of organizations want to follow the guidelines of these standards.

As there exist different management system standards for separate functional areas inside organizations (e.g., quality, health and safety, environment, etc.), implementation of these standards in one organization leads to creation of the integrated management system (see, e.g., Rebelo et al. 2016).

The ISO 14001 Standard: General Information

The ISO 14001 standard was based on the BS 7750 standard proposed in 1992 by the British

Standard Institution. It was first introduced in 1996 by the International Organization for Standardization (ISO) – current updated version comes from 2015. Typical way of referring to the standard is to present its name with the date of its publication, e.g., ISO 14001:2015.

The standard allows to build an environmental management system (EMS) based on the process approach. EMS is defined by the standard as part of the management system that is “used to manage environmental aspects, fulfil compliance obligations, and address risks and opportunities” (ISO 14001:2015).

One of the most important elements, as in ISO 9001 quality management system, is to imprint a process of continuous improvement in the functioning of an organization. The continuous improvement is carried out on the basis of the so-called Deming cycle consisted of four stages: plan, do, check, and act (PDCA cycle) (see, e.g., La Verde et al. 2019, p. 2).

Due to a periodical review practice maintained by ISO, management system standards are updated to ensure that they still meet the market needs. The last updating ISO introduced a significant change in the general management system structure, called the High-Level Structure, that helped to use the same structure and the same terms and definitions both by ISO 9001 and 14,001 standards as well as other ISO management system standards.

EMS standard according to ISO 14001 can help “organizations improve their environmental performance through more efficient use of resources and reduction of waste, gaining a competitive advantage and the trust of stakeholders.” (ISO 2015, p. 2; for further discussion on potential benefits, see, e.g., Tari et al. 2012).

Organizations that already implemented the standard have reported that it helps:

- “Demonstrate compliance with current and future statutory and regulatory requirements.
- Increase leadership involvement and engagement of employees.
- Improve company reputation and the confidence of stakeholders through strategic communication.

- Achieve strategic business aims by incorporating environmental issues into business management.
- Provide a competitive and financial advantage through improved efficiencies and reduced costs.
- Encourage better environmental performance of suppliers by integrating them into the organization's business systems" (ISO 2015, p. 4).

The family of ISO 14000 standards is much larger; it contains a number of documents supporting the implementation of an environmental management system. However, only the requirements formulated in the ISO 14001 standard constitute guidelines for an organization that wants to implement an environmental management system. Thanks to the compliance with this standard organizations can obtain independent confirmation of the implementation and maintenance of EMS through a system of certification and audits carried out by authorized certification bodies.

The Requirements of ISO 14001:2015

The main goal of the standard is to enable the organization to formulate its environmental policy and environmental objectives, taking into account formal and legal requirements and data on its environmental impact. The requirements of the standard have been defined so that they can be used by any organization, regardless of its size and environmental impact. The idea is to continuously improve the system and this way gradually reduce the organization's environmental impact.

Requirements for the environmental management system are divided into the following sections (Chapters 4–10): context of the organization, leadership, planning, support, operation, performance evaluation, and improvement. Below is a brief description of selected key elements of the environmental management system (ISO 14001:2015 and Reichel and Wójcik 2005).

Environmental policy is a declaration by top management regarding the organization's strategy

for environmental protection. The standard requires top management to issue self-commitment to continuous improvement, prevention of the pollution, and compliance with applicable legal requirements. The policy is the basis for determining environmental objectives and tasks. All employees should be aware of the policy, and it should also be publicly available.

As part of the planning processes, the standard requires the establishment of a procedure to identify environmental aspects related to its activities, products, and services and to designate significant environmental aspects from among them. These should be aspects that the organization can control. Objectives and tasks should be set based on significant aspects. Information on aspects should constantly be updated.

In addition, the standard requires also the creation of an legal requirements identification procedure and provision of access to legal regulations that apply to an organization and its environmental aspects.

Knowing environmental aspects and legal requirements, an organization can start to set environmental objectives and tasks. They should be regularly reviewed and documented.

An environmental management program is the result of the planning stage. It includes assigning responsibilities, financial resources, and deadlines for achieving planned objective and tasks. "A significant element influencing EMS improvement is the involvement of employees, without who even the most efficient top management is not able to realize the determined targets" (Gawaikar et al. 2018, pp. 637–638).

The implementation of the system should help to identify and ensure, among others:

- Resources, roles, responsibilities, and powers
- Appropriate competences, training and awareness
- Appropriate communication procedures for both internal and external communication
- The documentation required and supervision of this documentation
- Appropriate operational control ensuring that activities related to significant environmental aspects are planned and carried out under

supervised conditions based on relevant operational criteria

- Emergency preparedness and emergency response

Checking stage of the Deming cycle should be carried out by regular monitoring and measurement in relation to those operations and activities of the organization that may have a significant impact on the environment, periodic assessment of compliance with legal regulations, handling of detected and potential nonconformities, and taking corrective and preventive actions and internal audit of the environmental management system. The scale of corrective and preventive actions should be appropriate to the given problem.

Internal audit of the environmental management system is a method of testing the compliance of the system with the requirements of the standard, legal regulation, and own environmental policy and program. When preparing the audit plan, the environmental relevance of the activities considered and the results of previous audits should be taken into account. Areas where the risk of pollution is higher will be studied more often and more carefully by the audit team.

The culmination of the system is a management review, which is carried out by top management. Management reviews should be carried out periodically to ensure consistent usefulness and effectiveness of the system. They are used to assess the implementation of the environmental policy. The output from the review should provide input for the planning process. In this way, the principle of continuous system improvement is implemented.

From the above description, it can be concluded that the permanent application of the presented system should in effect lead to an improvement in the overall environmental impact of the organization.

Environmental Effects

Since the ISO 14001 Environmental Management System does not formulate any absolute level of achievements for environmental

performance, the question arises to what extent the implementation of the system and its functioning translate into positive environmental effects (Reichel and Wójcik 2005). Such a correlation between implementation of the EMS and positive environmental effects could mean that the standard can be treated as a tool to achieve sustainable development (see, e.g., da Fonseca 2015; and Rebelo et al. 2016).

“ISO 14001:2015 sets out the criteria for an environmental management system and can be certified to. It maps out a framework that a company or organization can follow to set up an effective environmental management system.” (ISO 2019). In the family of ISO 14000 standards regarding the environmental management system, there is a group of standards relating to the assessment of the organization’s environmental effects (e.g., ISO 14031:2013 and other from the ISO 14030 standards family dedicated to environmental performance evaluation). These standards do not present requirements to follow but describe a set of good practices and guidelines for monitoring the environmental performance of the organization.

Having the ISO 14001 Environmental Management System certificate is not synonymous with achieving better environmental effects than in the case of a similar organization that does not have such a certificate. Having a certificate only means that the organization manages its activities, products, and services that can have a significant impact on the environment by using effective environmental management system. In the long run, we should certainly be able to see the positive effects of such good management. Of course, the organization is not forced to apply for certification to be able to use the good environmental management practices described in the standard. The organization can self-declare to stakeholders that have implemented and is maintaining the environmental management system. However, independent and objective verification by the external auditors of the certification body is generally more objective and credible than such own self-declaration. That is why many organizations try to obtain such external confirmation in the form of a certificate,

especially when it is relevant for interested parties, e.g., contractors or customers.

Summary

ISO 14001:2015 standard published by the International Organization for Standardization (ISO) presents requirements for establishing an environmental management system. This management system standard is well recognized by the international community as an effective way of management of organization that can contribute to sustainability. The standard enabled organization to establish its environmental policy, identify and manage environmental aspects, and implement its environmental programs using preventive approach to the protection of the environment. The standard can be a subject of certification.

Definition

ISO 20121 is a voluntary International Standard for sustainable event management created by the International Organization for Standardization (ISO) in 2012.

Introduction

ISO 20121 (full name ISO 20121:2012, *Event sustainability management systems – Requirements with guidance for use*) is a voluntary International Standard for sustainable event management created by the International Organization for Standardization (ISO) in 2012. ISO 20121 was first adopted by the London 2012 Olympics, which acted as a catalyst for the formation of the Standard. The creation of the Standard directed the event industry toward a proactive approach in search of innovative solutions on how to address sustainability issues through an internationally recognized framework.

The aim of the Standard is to help organizations better meet sustainability objectives throughout the entire event management cycle. The Standard is applicable to all events, regardless of size, location, and theme. The Standard integrates the typical management system (MS) adopted by other Standards, like ISO 9000 and ISO 14000: the PDCA (plan, do, check, act) model. This allows easy integration with other ISO certification schemes. ISO 20121 provides a useful framework to manage and reduce potentially negative social, economic, and environmental impacts of events, helping organizers to leave a sustainable legacy to the hosting community and improving relations with all stakeholders.

The International Organization for Standardization (ISO)

The International Organization for Standardization (ISO) is an independent nongovernmental organization (NGO) founded in 1947. The initialism ISO was set and chosen because “isos” in Greek means equal, given that the full name

would have been abridged using different initialisms in different languages, e.g., IOS in English (for “International Organization for Standardization”) or OIN in French (for “Organization Internationale de Normalisation”). Consequently, the short form ISO is now adopted in every country. The organization has its headquarters in Geneva, Switzerland. The ISO can truly be considered an international NGO having a membership of over 160 national standards bodies (ISO member bodies). The ISO also works in close partnership with an array of governmental and nongovernmental international organization.

The goal of the ISO is to bring together experts to share knowledge and to develop voluntary International Standards and facilitate their diffusion and adoption worldwide. The breath of the membership ensures a wide consensus while providing innovative solutions to global challenges. An International Standard is “a document containing practical information and best practices. It often describes an agreed way of doing something or a solution to a global problem” (<http://www.iso.org>). At the end of 2018, ISO had published over 22,500 International Standards, covering almost all aspects of technology and manufacturing. ISO 9000, *Quality Management*; ISO 22000, *Food Safety Management*; and ISO 14000, *Environmental Management* are among the most popular International Standards issued by ISO.

While its main aim is developing International Standards, the ISO itself does not perform conformity assessments and does not issue certifications of compliance with the Standards. The certifications are issued by external certification bodies. Even if not compulsory, it is strongly suggested that certification bodies should be accredited. Accreditation is the formal recognition by an independent accreditation body that a certification body operates according to International Standards.

History of ISO 20121

At the beginning of the new millennium, awareness of the importance of sustainability had

already spread in many industries. This awareness first became apparent in sectors with material outputs where sustainability impacts (mostly environmental) were more visible before spreading to service industries.

In the field of event organization, a key role was played by David Stubbs, the Head of Sustainability at the London 2012 Olympic and Paralympic Games. He was not only strongly committed to moving the organization of the Olympic Games toward sustainable management practices but also convinced of the importance of transparently showing and objectively measuring this commitment. Thus, shortly after London won the right to host the 2012 Olympics in July 2005, a partnership was established between the London Organising Committee and the British Standards Institution (BSI) in the UK to elaborate a Standard in the field of event sustainability. In 2006 the BSI began to work on the project, and in 2007 the Standard BS 8901:2007 *Specification for a sustainable event management system with guidance for use* was firstly issued. After a period of review, the second version of the Standard was published in 2009. The Standard received positive reactions from the practitioners' community, and in 2009 other important events in the UK, Europe more widely, and North America were BS 8901 certified, for example, the Microsoft Convergence event held in New Orleans in March 2009 and the United Nations Conference on Climate Change COP15 held in Copenhagen in December 2009.

Following the interest of the event industry, the BSI together with the Brazilian National Standards Organization (Associação Brasileira de Normas Técnicas – ABNT) submitted a proposal for an International Standard on sustainable event management to the International Organization for Standardization (ISO). The work of preparing International Standards is normally carried out through ISO technical committees. Here, the first draft was prepared by Project Committee ISO/PC 250, Sustainability in Event Management. A large group of stakeholders was included among the experts providing inputs for the Standard, including the delegations of the national standards institutions of 25 countries, NGOs

committed to sustainability, representatives from the event industry, and members of the sustainability team of the London 2012 Olympics. The Standard ISO 20121:2012 *Event sustainability management systems – Requirements with guidance for use* was first issued in June 2012.

Consistent with its highly influential role in the launch of the Standard, the London Organising Committee of the Olympic and Paralympic Games (LOGOC) and the Olympic Delivery Authority were among the first to be ISO 20121 certified, indeed this occurred in the same month that Standard was issued, June 2012.

Today, ISO 20121 is one of the main Standards in the field of sustainable event management, together with the Global Reporting Initiative's (GRI's) Sector Supplement for events (Buathong and Lai 2017; Musgrave and Henderson 2015) (see ► [“Global Reporting Initiative”](#)).

Content of the ISO 20121 Standard and the Certification Process

Every event has economic, social, and environmental impacts, even if the size of the event has a significant influence on the dimension of these impacts. Major and mega-events can put pressure on water and energy resources, generate significant amounts of waste and carbon emissions, provoke inconveniences for local communities, exacerbate urban traffic, and put a strain on the ordinary running of the economic activities of a territory (Andersson and Lundberg 2013). Meanwhile, some characteristics of the event industry can make it challenging to deal with sustainability issues, because a special event is by definition unique and temporary.

The ISO 20121 Standard provides a common framework for the event industry to manage its social, economic, and environmental impacts and is designed to be relevant for all types of event, from a small local music festival to the Olympic Games. The Standard is directed above all – but not exclusively – toward organizations having as their core business the organization of events (e.g., congress centers, communication agencies, trade fair areas, theatres, and local events

organizers). It has the purpose to individuate the potentially negative externalities of events, considering the whole management system from the project to the realization of the event. This way, it allows removal or reduction of these negative impacts through the adoption of adequate planning and processes consistent with key sustainability issues and in line with the goal of continuously improving management systems. The ISO 20121 Standard also includes practical guidance on stakeholder identification and engagement, supply chain management and procurement, and communication. The content of the Standard also includes elements of ISO 14000, *Environmental Management* and ISO 26000, *Social Responsibility*, exploiting the synergies among different International Standards (see ► “ISO 26000 Standard”).

The Standard is based on the plan-do-check-act (PDCA) model and can be easily integrated with other International Standards based on this typical management system, as per ISO 9000 (see ISO 9000). The PDCA management system model is combined with the event's life cycle as attention toward sustainability is raised in every stage of event management (Toniolo et al. 2017): projecting, planning, staging, closing and dismantling, controlling, and feedback. The widest possible number of stakeholders should be engaged in the process, to ensure the identification and addressing of all significant issues. This would allow meeting the expectations of the interested parties in terms of sustainable development. The PDCA management system model adopted by ISO 20121 is presented in Fig. 1.

Following this management system model, the organization will be able to identify the key issues and outline its commitment toward sustainability, developing specific objectives and targets. Consequently, staff can be appropriately trained, and suppliers can be made aware of and engaged with sustainability. It is also necessary to develop a sustainability communication plan to disclose the process to all interested stakeholders. Finally, the results have to be monitored and measured.

The Standard adopts an approach to sustainability based on the triple bottom line, as identified by Elkington (1997), and the content

considers a wide number of key issues related to sustainability, covering

- (a) Environmental aspects – emissions' reduction in air, water, and land; recycling and reusing; resource conservation; respect for the environment and biodiversity; materials' choice; energy consumption; waste reduction
- (b) Social aspects – civil rights; equal opportunities; respect for the local community; health and safety; labor rights; respect of all cultures and religions; discrimination and respect for minorities
- (c) Economic aspects – direct and indirect economic impacts; effects on the local economy; risks and profits; return on investment; fair trade; profit sharing

Appropriate management of these aspects should lead to enhanced event sustainability through appropriate venue selection, transport policy, logistics optimization, supply chain involvement, staff training, employee empowerment, and maximization of positive legacy (Chirieleison et al. 2019; Gregori et al. 2018).

To demonstrate conformity with ISO 20121, an organization can be certified by an independent certification body. However, besides third-party certification, the Standard also allows a first party self-declaration or a second party confirmation of conformance released by relevant stakeholders (e.g., clients). Opting for certification by an independent third party provides a wider assurance regarding the MS and is generally considered more reliable than self-evaluation or second party confirmation by stakeholders.

The certification process involves three steps. The first step is a pre-evaluation audit, which is optional as at this stage an organization can pursue a check of the Standard's requirements through internal auditing. The second step is the certification audit by an independent accredited certification body, providing both the first stage of the documental audit and the second stage of on-field audit. If the organization complies with the Standard, the certification body issues a certificate. The third step is the annual audit to maintain

**ISO 20121 Standard
(Event Sustainability),**

Fig. 1 PDCA management
system model adopted by
ISO 20121

the certification. Once issued, a certificate is valid for 3 years and then expires, and organizations must once again be subjected to the full certification process to become recertified.

The temporary nature of events can create peculiarities in the certification process respect compared to that where organizations have continuous activity. In many cases, a large part of sustainability impacts can be evaluated only after the event's closing. But that would make the

certification practically useless if it is issued only after the conclusion of the event. Thus, even if the audit activities are related to three phases of the management system – planning, monitoring, and reporting – just the planning has to be mandatorily audited before certificate issuance, while the monitoring and reporting phases can be audited in a second step, when available. Peculiarities can also arise regarding the duration of the certificate; the 3-year validity

period can be shorter in case of events with limited duration and non-periodical events.

Certifiable Organizations

ISO 20121 provides a framework for all members of the event supply chain and is suitable for all sizes – from mega-events to small happenings – and types of events, including sport, culture, and business events, on a voluntary basis. An organization could implement the Standard for the management system of a single event (e.g., a single sport event or a convention), for a group of events (e.g., a periodical festival or all the events organized by the same communication agency), or just for its management system with no specific reference to the certificate to any event. In this latter case, certification is only intended for the organization responsible for the sustainable MS.

The Standard is directed to three types of organizations:

First, all organizations having event management as part of their core business (e.g., events' organizers businesses and communication agencies) and organizations wishing to improve the sustainability of their own events (e.g., corporations)

Second, suppliers to the event industry who provide products or services (e.g., catering, security, energy, temporary workers providers, stewards, and stand builders)

Third, structures for events (e.g., congress centers, hotels, trade fair areas, stadia, and sports complexes)

Given its nature and the significant costs necessary to obtain the certification, ISO 20121 is mainly adopted by large size events with an international public, having the need to demonstrate their commitment toward sustainability as part of their reputation and legitimacy (Andersson 2016). Recent examples of certified events are the Åre 2019 FIS Alpine World Ski Championships, the Expo 2015 World's Fair, and the PyeongChang 2018 Winter Olympics. However, dozens of smaller size events worldwide are ISO 20121

certified such as the Sydney Festival in Australia and the Tocati Festival in Italy.

Benefits and Criticalities of the ISO 20121 Standard

The Standard's adoption can benefit the image and reputation of the organization, contributing to demonstrate a high commitment toward sustainability in a credible and transparent way. It can also help to build strong relations with stakeholders, partners, suppliers, and local communities thus facilitating event organization. Achieving the certification can also be a part of a differentiation strategy, helping to stand out from competitors. Moreover, emphasis on continual improvement contributes to enhancing the effectiveness of managerial competencies and skills highlighting the importance of good business practices. Finally, ISO 20121 adoption can significantly contribute to cost savings, by virtue of reduced power consumption, better waste management, recycling, and risk reduction (Hall 2012).

Even if adoption of ISO 20121 can undoubtedly contribute to moving the event industry toward a management system conducive to sustainable development, it's not immune from criticism.

Considering the general approach of the framework, the Standard deals with a management system approach to running more sustainable events, but sustainability is mainly operationalized as the reduction of negative externalities, while the aspect of maximizing positive externalities and leaving a progressive legacy is largely neglected (Lienhard and Preuss 2014).

Moreover, regarding the contents of the Standard – as often happens when dealing with sustainability – the emphasis on the environmental dimension is much higher than that on the social and economic dimensions.

Finally, a certain ambiguity on the real object of the certification emerges. It's worth noting that it is not the event itself nor the organizer which will be declared in conformity with the Standard, but rather the management system. Thus,

certificate issuance does not guarantee that a certain event has low negative externalities nor that it is a green event.

Summary

ISO 20121 is a voluntary International Standard for sustainable event management. It has the purpose to promote a proactive approach in the event industry for addressing sustainability issues. ISO 20121 applies to all events, regardless of size, location, and theme. Adoption of the Standard can benefit the image and reputation of the certified organization.

University of Urbino Carlo Bo, Urbino, Italy

Synonyms

Corporate social responsibility (CSR) guidance,
Socially responsible management standard,
Socially responsible practices

Definition

ISO 26000 is a guidance released by the International Organization for Standardization aimed at supporting all types of organizations in implementing and assessing socially responsible (SR) practices. It has been conceived as a tool capable to drive companies toward a sustainability-oriented management. ISO 26000 is “useful to

all types of organisations in the private, public and non-profit sectors, whether large or small, and whether operating in developed or developing countries” (ISO 2010, iv).

Unlike many international guidelines (such as the Global Reporting Initiative – GRI, among others) and norms (i.e., the SA – social accountability – 8000 standard) that are aimed to provide a set of rules to release a reporting tool or a certification, ISO 26000 is directed to allow organizations address their attention on socially responsible principles and behaviors, operationalize and communicate responsible practices and policies, and communicate performance and other information related to social responsibility actions. Among the benefits deriving from ISO 26000 implementation, one can mention both internal and external benefits, as well as intangible and tangible ones, such as, among others: an increase in company reputation and internal climate; a growth in the capability to attract and retain employees and customers; a reduction in the cost of capital due to disclosure and transparency; and better relationships with stakeholders (ISO 2012).

Introduction

The first ISO 26000 guidance was released in 2010. In the subsequent years the UNI and the Sodalitas Foundation started a renewed journey to better frame the guidance and render it consistent with the concrete needs and expectations of companies interested in enhancing their responsibility-driven approach. Namely, a series of reflections and suggestions have been provided, thus contributing to release a renewed version of the guidance, the “UNI ISO26000: social responsibility in practice” in 2016. The latter can be considered the output of a shared (multilevel and multistakeholders) process based on the direct involvement of companies belonging to different sectors (i.e., mechanics, energy, and finance) whose experiences were presented on January 30, 2014 during a conference “Measuring to improve. UNI ISO 26000: comparing approaches and experiences,” held in collaboration with

Bureau Veritas and DNV-GL Business Assurance, among others (UNI and Sodalitas 2014). During the following months, a growing number of organizations demonstrated their interest in being involved in focus groups composed by selected stakeholders and company’s experts called to share and improve the fundamental themes of ISO 26000, including accountability, SR performance, and stakeholder engagement (Balzarova and Castka 2012). The feedback of this participatory process led to elaborate the current practical guidance conceived as a reference point for two type of companies and organizations. The first type includes entities characterized by an unstructured or a limited and initial approach to social responsibility that – however – feel motivated to strengthen their approach and in particular their methodological skills. The second one includes companies and organizations that have already performed a mature and structured approach to CSR. In these contexts, the guidance proves useful to effectively address specific aspects, overcome critical issues, and manage most complex situations.

Namely, the latest ISO 26000 version – released in April 2016 (UNI/PdR 2016), intends to concretely helps organizations to adopt a socially responsible approach through a step-by-step process, starting from the identification of company’s stakeholders to their active engagement in defining SR strategies and operationalizing SR objectives. The second step consists in evaluating the actual and potential impacts of the company’s decisions and actions on stakeholders and the society at large, while the third is focused on how SR can be integrated in the company’s strategy and culture and on the tools to be used to communicate and improve the socially responsible policies and actions.

Key Issues

ISO 26000 underpins the concept of corporate social responsibility (CSR) promoted by the European Commission since it is finalized to drive companies toward a sustainability-oriented management process by addressing their attention on

seven fundamental principles: accountability, transparency, ethical behavior, respect for the law and international norms of behavior, and respect for human rights and stakeholders' interests.

The guidance also points out seven areas of SR (the so-called "seven core subjects") that comprise a variety of issues: governance (company structure and decisional mechanisms); human rights (civil, political, economic, social, and cultural rights); labor practices (i.e., working conditions and relations, training, etc.); environment (i.e., environmental protection and pollution prevention); fair operating practices (fight against corruption, loyal competition, etc.); consumer issues (i.e., consumers' health safeguard, services and support for consumers, etc.); and community involvement and development (i.e., social investment in education culture, etc.) (ISO 2010). These themes must be treated holistically because they are interrelated and complementary in nature.

The ISO 26000 guidance illustrates how to approach the aforementioned pillars and themes and emphasizes those particularly critical relative to materiality, accountability, and stakeholder engagement. Moreover, a great attention is paid to the governance since it is fundamental that the top management triggers the adoption of a systematic approach to SR and spreads this orientation inside the organization by involving and raising the awareness of directors and heads of departments and, in turn, all the employees.

The top management involvement path unfolds through a motivational phase, supported by the method of storytelling, and a phase of SWOT analysis, which helps to carry out a context analysis. Drawing from the results derived from the telling and SWOT analysis, an action plan based on a socially responsible approach should be delivered, oriented towards the medium to long term. Starting from the strategic documents, such as the code of ethics and the organization's policies, the top management should be involved in operationalize each of the seven fundamental themes of UNI ISO 26000, in identifying specific objectives, to be implemented (action plan) and a set of indicators (KPIs) to measure the progress of

the action plan and the achievement of the targets (UNI/PdR 2016).

ISO26000 contributes to improve existing practices and strengthens the integration of SR into the organization and the business model. Therefore, a central issue is to solicit the company's transition from a sporadic and extemporaneous approach to a systematic and integrated approach that can be achieved through the creation of a governance system of SR (Hahn 2013). The guidance includes practical and friendly tools, such as a checklist for the governance assessment as well as useful examples to operationalize the materiality process (i.e., the questionnaire for the materiality analysis).

Several contributions have pointed out that ISO 26000 implementation can increase transparency and disclosure, improve governance, and engage stakeholders. In other words, it has the potential to allow organizations to reframe their strategic approach to CSR (Moratis and Cochius 2011; Moratis 2016a). However, some authors have highlighted that there are also critical issues, affecting both the process adopted to release the guidance and its implementation (Johnston 2011). The former are linked to the prevalence of industry representatives over other categories of stakeholders (Schwartz and Tilling 2009). The latter are relative to the growing diffusion among multinational companies that makes the guidance more suitable to large corporations rather than small- and medium-sized enterprises (Balzarova and Castka 2012). In such contexts the implementation of the guidance is instead slowed down or prevented by the lack of time and resources (Perera 2008). Finally, ISO 26000 has been considered too broad in scope to be consistent with specific industries and sectors (De Deus et al. 2014) and suffers from the lack of a formal certification suitable for contractual use (Moratis 2016b).

Future Directions

ISO 26000 does not overlap existing standards. Rather, it encourages companies' leaders to direct their attention to social responsibility core subjects (Zinenko et al. 2015) by complementing

existing tools that have different goals. Therefore, when a company already adopts other sustainability frameworks, standards, and tools (i.e., ethical codes, GRI, and integrated reporting framework) ISO 26000 can be useful to assess the possible gaps in their current practices (Hemphill 2013). In addition, the guidance is particularly suitable to integrate SR activities in the core business of companies that are new to social responsibility practices and strategies.

In addition, ISO 26000 proves to be adaptable to different contexts. In this regard the growing diffusion of ISO 26000 among companies that are different in size, sector, public and private ownership demonstrates. This key attribute, in addition to the positive image of ISO as a globally reputable and credible organization derived from a broad-based development process (Hahn and Weidtmann 2016), gives reason for its high international consensus and degree of legitimacy, thus rendering ISO 26000 an important guide for firms worldwide (Zompras and Siakas 2015).

Summary

ISO 26000 is considered a principle-based guidance that attempts to operationalize SR principles by providing suggestions for a concrete implementation. As a “practice of reference,” it is intended for use by all organization, thus including both the ones that are starting the CSR journey and those that are more experienced with its implementation. ISO 26000 represents a practical tool companies may use to assess if and how they are achieving sustainability goals. It thus concretely contributes to their strategic management and governance betterment.

ISO 31000: Risk Management Guidelines

Dragana Makajić-Nikolić

Faculty of Organizational Sciences, University of Belgrade, Beograd, Serbia

Synonyms

Crisis management; Hazard management; Uncertainty management

Definition/Description

The first standard concerning risk management was ISO 31010:2009 “Risk management – Principles and guidelines (ISO/IEC 2009b).” It was later revised and published as ISO 31000:2018 “Risk management – Guidelines.” The main reason of revision was the necessity to include the increased complexity in business caused primarily by the development of information technology. Standards related to ISO 31000 are: ISO/TR 31004:2013 “Risk management – Guidance for the implementation of ISO 31000,” ISO Guide 73:2009 “Risk management – Vocabulary (ISO/IEC 2009c),” IEC 31010:2019 “Risk management – Risk assessment techniques (ISO/IEC 2009a),” and NP IWA 31 “Using ISO 31000 guidance on risk management in management systems.” ISO/TR 31004 is a technical report that provides guidance for organizations to create

risk management system consistent with ISO 31000. ISO Guide 73 gives the definitions of terms that refers to the risk management. A new version ISO/AWI 31073 “Risk management – Vocabulary” is in the proposal stage (ISO/IEC 2019c). IEC 31010 is related to risk assessment techniques which goal is to identify and analyze risks in order to determine whether and what kind of treatment should be conducted (ISO/IEC 2009a). The Technical Committee ISO/TC 262–Risk management is preparing several new standards in the 31000 series: ISO/DIS 31022 “Risk management – Guidelines for the management of legal risk” is in the enquiry stage” (ISO/IEC 2019d); ISO/WD 31070 “Risk Management – Guidelines on core concepts” (ISO/IEC 2019f) and ISO/AWI 31030 “Risk management – Managing travel risks – Guidance for organizations” (ISO/IEC 2019b) are in the preparatory stage; and ISO/NP 31050 “Guidance for managing emerging risks to enhance resilience” (ISO/IEC 2019e) are in the proposal stage.

Introduction

According to ISO 31000:2018, risk is “effect of uncertainty on objectives.” This definition can be extended as follows: “the effect of uncertainty on an organization’s ability to meet its objectives.” Besides ISO, numerous authors have given the definitions of risk. In the literature on risk management, the oldest definitions that can be found are: “Risk is a measure of the likelihood and severity of unwanted events” (Lawrence 1976) and “Risk depends on three variables (si, pi, ci), where si represents the scenario, pi is the probability of the i-th scenario, and ci is the consequence of the i-th scenario, $i = 1, 2, \dots, n$ ” (Kaplan and Garrick 1981); while some of the most cited definitions are: “Risk is the probability that exposure to a hazard will lead to a negative consequence” (Ropeik and Gray 2002) and “Risk = probability x severity” (Ericson 2015). Although these definitions are formulated differently, a common feature of all is to consist of two components: the probability of some undesired event and its consequences. These two components are also included

into latest definitions such as: “Risk is a measure of the probability and consequence of uncertain future events” (Yoe 2019) and “Risk is relates to a specific event or scenario and to two of its components: probability/certainty/likelihood of the event and the severity of its (negative) effects” (Makajić-Nikolić 2020). Consequently, risk management defines and conducts a set of activities with aim to define measures that will affect these two components to reduce risk.

Risk Management

ISO 31000 International Standards Series observe risk management as an iterative process consisting of “coordinated activities to direct and control an organization with regard to risk” (ISO/IEC 2018). ISO 3100 defines risk management principles, framework, and process. Changes in the version ISO 31000: 2018 in relation to ISO 31000: 2009 primarily refer to the review of risk management principles and highlighting the importance of leadership by top management. The iterative nature of risk management is emphasized, which implies that revision is necessary with each acquisition of new experience and knowledge.

Risk management is based on eight principles. According to these principles, it should be: integrated in all organization activities; structured and comprehensive; customized to the external and internal contexts; inclusive, in terms that stakeholders should be involved; dynamic in the sense that it follows all internal and external changes; based on best available information; influenced by cultural and human factors; and constantly improved.

In order to help organizations in integrating risk management, a framework, based on leadership and commitment, has been proposed (ISO/IEC 2018). This framework guides the organization through six components towards the final result: integrated, effective, and efficient risk management. The component named integration is related to the activities that will enable further integration of risk management into all organization's parts. Thereafter, design component should provide conditions for assigning roles, responsibilities, and

authorities for the risk management process and allocation of required resources. A prerequisite for successful design is a thorough examination of external and internal risk management context. The implementation component of risk management framework involves developing detailed plans that include time and resources as well as the types of decisions to be made in particular segments of the organization. The role of evaluation components is to measure risk management performance and evaluates the effectiveness of decision concerning risk management. Once a risk management system is established, it must constantly be adjusted to external and internal changes (improvement component).

According to (ISO/IEC 2018) and (ISO/IEC 2019), risk management process consists of four main stages:

- Defining scope, context, and criteria of risk management. At this stage, the level of organization (strategic, operational, project, etc) to which the risk assessment will be applied must be defined and external/internal context should be examined. Finally, risk assessment criteria must be determined relating to: measures for probability and consequences, uncertainty influence, time-related factors, resources capacities, etc.
- Risk assessment can be considered crucial stage of the risk management process since the decisions and activities that should be implemented depend most on its results. Standard IEC 31010 offers a list of 41 risk assessment techniques, methods, and approaches grouped by the following purposes (ISO/IEC 2019): eliciting views; identifying risk; determining sources, causes, and drivers of risk; analyzing controls; analyzing dependencies; providing a measure of risk; evaluating the significance of risk; selecting between options; and recording and reporting. In addition, techniques are classified according to their applicability in the steps of the risk assessment process: risk identification, probability analysis, consequence analysis, analysis the level of risk, and risk evaluation. All these techniques differ according to: ability to solve complex

problem, possibility to deal with uncertainty, resources requirements, and type of outputs – qualitative or quantitative.

- Risk treatment. At this stage, risk treatment options as well as the plan of their implementation should be defined. Risk treatment option can be single action or combination of the following actions: removing the risky activities or their sources, reducing the probability of risk, mitigate the consequences, sharing the risk through insurance or contracts, retaining the risk.
- Recording and reporting all outcomes of risk management process.

The entire risk management process is conducted through communication and consultation with all relevant stakeholders and constantly monitored and reviewed.

Summary

Risk management is a part of all organization's activities and includes constant interaction with stakeholders with goal to improve entire management system. ISO 31000 International Standards Series for Risk Management clearly indicates that risk management is an iterative process and that once-established risk management is only a baseline that must be constantly monitored and reviewed. An additional reasons for the continuous review of risk management are accelerated and turbulent market changes driven by new business paradigms and information technologies development. The announcement of new standards in this series confirms the awareness of the relevant institutions of present and future challenges.

Anti-bribery and corruption (ABC) compliance programs; Anti-bribery management system standard; Anti-Corruption Management Systems; ISO 37001

Definition/Description

ISO 37001:2016 is an international management system standard against bribery, issued by the International Organization for Standardization (ISO). The aim of the standard is to support companies and organizations in combating bribery risks in their own operations and in their global value chains to prevent and detect bribery and to create international comparability in anti-corruption management.

ISO itself is the international association of more than 160 national standardization bodies that work together in ISO technical committees to develop international standards. ISO Standard 37001 was published for the first time on 15 October 2016 under the title “Anti-bribery management systems – Requirements with guidance for use”. ISO 37001 is based on the British standard 10500 and refers to international anti-

corruption principles and guidelines. The standard is open to all types of organizations, regardless of their size, legal form, or geographical location. ISO 37001 has the usual “high-level structure” of an ISO standard, which simplifies setting up and operating the system alongside other management systems in an organization. As a Type-A standard, ISO 37001 is approved for certification. Companies can ask to be certified by accredited third parties; thus proving that their anti-bribery management system meets the criteria of the ISO 37001 standard. However, neither appropriate certification nor basic conformity to ISO 37001 can guarantee that bribery does not occur. Instead, the certification of a management system indicates that the company has taken all appropriate and required measures to tackle the issue of bribery.

Introduction

In 2018, the United Nations estimated that one trillion dollars are paid in bribes annually. According to the UN, corruption is one of the biggest obstacles worldwide on the road to achieving the Sustainable Development Goals (SDGs) of the 2030 Agenda (Schuler 2018).

In the following text, the terms “bribery” and “corruption” are used synonymously. It is noted that ISO points out the semantic difference between corruption and bribery (ISO/TC 2017). However, the title of the German and French editions of the standard refers to anti-corruption.

Against this background, ISO 37001 (ISO 2016; hereafter cited with “37001” and indication of section and page) has two aims: first, to create a common understanding of bribery and second, to set standards for the establishment, regular revision, and improvement of an internal anti-bribery management system. ISO 37001 applies a broad definition of bribery acts (Makowicz 2018a, p. 20), as it includes, both, the public and private sectors, the nonprofit sector as well as active and passive corruption (Brescia 2017, p. 6; cf. Myrdal 1989, p. 405).

Bribery is

[...] *offering, promising, giving, accepting or soliciting of an undue advantage of any value (which could be financial or non-financial), directly or indirectly, and irrespective of location(s), in violation of applicable law, as an inducement or reward for a person acting or refraining from acting in relation to the performance of that person's duties.* (37001, 3.1, p. 2)

The authors of the standards note that their definition is a general, wide-encompassing definition. Applicable national law and the anti-corruption management system, individually developed by the company, define the further meaning of the term “bribery” (37001, Note 1).

The introductory text of the standard highlights that bribery is a global phenomenon and that laws alone are insufficient to combat these offences that cause damage in countries as well as organizations and harm individuals. The ISO calls on private and public companies to play an active role in the fight against corruption by proactively developing anti-bribery and anti-corruption programs and extending them to their business partners (Crescenzi 2018, p. 37).

ISO 37001 is published by the International Organization for Standardization (ISO), a non-governmental organization based in Geneva, Switzerland. Founded in 1947, ISO works with more than 700 international and regional organizations in 162 countries to promote global trade and improve the management of business processes by establishing international business standards (Crescenzi 2018, p. 36; ISO 2018, p. 8). By November 2020, 23,528 international standards and related documents were published; covering almost every industry, e.g., technology, food safety, agriculture, and healthcare (ISO 2020a). The ISO 9001 for quality management system (ISO 2015) is the world's most established ISO standard, currently being used by over one million organizations in 178 countries. The second most popular global standard is the environmental management system ISO 14001 (Stansbury 2016).

ISO 37001 was first published on October 15, 2016 under the title “Anti-bribery management systems – Requirements with guidance for use.” It contains the “requirements [that] are general

and are applicable to any organization (or part of the organization), regardless of the type, size, and nature of the activity” (Brescia 2017, p. 5). Each ISO standard must be globally applicable. The intention of ISO 37001 is to help organizations to minimize, detect, and respond to risks of corruption and to comply with anti-corruption laws and other voluntary commitments like the UN Global Compact (UNGC). The UNGC as a voluntary initiative was first presented by Kofi Annan in 1999 and “intended to increase and to diffuse the benefits of global economic development through voluntary corporate policies and actions” (Williams 2004, p. 755). Nine Principles were formulated, which companies commit themselves to meet by joining the pact. In June 2004, after the 2003 UN Convention Against Corruption was released, the UNGC added a tenth principle on combatting corruption (Williams 2004, pp. 755–56).

ISO 37001 addresses corruption by ignoring other fraud patterns and forms of company misconduct, e.g., fraud, cartels, and money laundering, as well as other anticompetitive practices. However, a company that complies with the standard may decide to extend the scope of its management system to include the prevention of such compliance violations (see also Grueninger and Kissmehl 2021).

In principle, the anti-bribery management system can be independent or integrated into an overall management system; it is also possible to operate as part of another management system, e.g., quality management, environmental protection, or information security (37001, A.2.1, p. 23). Many companies have already implemented a compliance management system with internal systems and processes to ensure the legal conformity of their business.

ISO 37001 defines a management system as a “set of interrelated or interacting elements of an organization to establish policies and objectives, and processes to achieve those objectives” (37001, 3.5, p. 2). The standard specifies the components of an anti-corruption compliance system that gears to continuous development and improvement in the sense of the “Deming Cycle,” “PDCA or PDSA Cycle” (Makowicz 2018a, p. 70 f.; Moen and Norman 2010).

ISO 37001 cannot prevent current or future cases of corruption. Nevertheless, the standards' advantage is its emphasis on a systematic approach to reduce the risk of corruption within companies. All organizational and procedural activities should be planned, coordinated, lived, documented, and monitored (Breit et al. 2018, p. 11). The effective implementation of an anti-corruption management system shows that a company has done everything that is reasonably possible proportionally to its size and risks to prevent the occurrence of corruption cases (37001, p. 23). However, this does not preclude individuals from working against an established system, infiltrating it for personal enrichment, or achieving business goals in an unfair manner by paying bribes (Breit et al. 2018, p. 11). The company's robust anti-corruption management enables these illegal activities to be detected quickly and further corruption crimes to be prevented.

The Development Process

Over the past 20 years, various international laws and procedures were developed to combat bribery. Illustrative examples are the OECD Convention on Combating Bribery of Foreign Public Officials in International Business Transactions (1997) and the United Nations Convention against Corruption (United Nations 2004). To meet the objectives of these Treaties most countries have either amended or adopted new domestic legislation. Since 1977, the US Foreign Corrupt Practices Act (FCPA) has been in force, whom companies which are involved in corrupt activities fear. The UK Bribery Act (UKBA 2010) entered into force on 1 July 2011. The UKBA has a global scope and applies sanctions to both, individuals and companies who have committed a bribery offence at home or abroad and are connected with the UK. After the adoption of the British Bribery Act, investigations worldwide were conducted against companies and individuals accused of bribery (Eberhardt 2018). Subsequently, the National Standards Body of the UK published the British standard BS 10500 ("Specification for an anti-bribery management system (ABMS)") in 2011 (British Standards Institution

2011). This standard that can be used by companies of a different type, size and sector contains minimum requirements and formulates the possibility of an independent review of a company's anti-corruption management. Building on the British standard, ISO 2013 established a committee to develop a new ISO standard for anti-corruption management systems in a multi-stakeholder process. Neill Stansbury, a British construction lawyer previously responsible for the development of the British standard BS 10500, chaired the Project Committee (Crescenzi 2018, p. 37). In principle, every ISO member body has the right to participate in a technical committee set up for a specific topic. In addition, both governmental and nongovernmental international organizations take part in the corresponding consultation processes (Ehnert 2015, p. 9).

The ISO 37001 is based on different international publications, best practices guidelines and publications of government institutions (Crescenzi 2018, p. 38).

In March 2014, the first meeting of the ISO Committee 278 was held in Madrid. Countries that Transparency International classifies as susceptible to corruption also contributed to the norm's development process. This signals that the fight against corruption has gained importance even for those countries (Kayser and Grueninger 2015, p. 135). In accordance with the usual procedure, the national standards institutes and their working committees (Ehnert 2015, p. 9) were able to submit their comments on the draft committee standard in between the meetings of the project committee.

After a second meeting in Miami, the project committee agreed at the third meeting in Paris in March 2015 with 46 countries participating that ISO 37001 would be a certifiable requirements standard (Kayser 2015, p. 441). Following the fourth meeting in September 2015 in Kuala Lumpur, the Draft International Standard (DIS) was submitted to the ISO member organizations and the national committees for discussion. The experts had previously adopted the version by consensus. Draft ISO standards can be purchased by anyone. After the public deliberation stage, minor corrections were made and the standard was finally published in October 2016 (Kayser 2017, p. 1).

Structure and Content

ISO 37001:2016 is based on the following three core concepts (Makowicz 2018a, p. 67): risk management system, PDCA cycle (Makowicz 2018a, p. 70), and ISO High Level Structure (HLS). The HLS is a standardized basic structure for all ISO management standards (ISO/IEC 2020), regardless of their subject area. This uniform content structure with identical chapter heading and a shared basic vocabulary allows the standard to be implemented in the organization either alongside other ISO management systems or to be combined into an integrated management system.

All management standards, structured according to the HLS, consist of ten sections. ISO 37001 covers these sections on 22 pages. While the chapters 1–3 serve as an introduction and contain the scope of the standard, references, and definitions of terms, the remaining chapters follow the Plan-Do-Check-Act approach (PDCA) and the principles “Establish” (chapters 4–7), “Implement” (chapter 8), “Maintain” (chapter 9), and “Improve” (chapter 10) (Breit et al. 2018, p. 11). PDCA operates as a cycle of continuous improvement with risk-based thinking at each stage (ISO 9001:2015, p. 2).

High-level-structure: P-D-C-A	Meaning	Content of the 37001
1. Scope (p. 1)	This section describes the scope of the standard	The norm provides guidance for organizations – regardless of type, size, and nature of activity – “ <i>to prevent, detect and respond to bribery [. . .].</i> ” (37001, S.1)
2. Normative references (p. 1)	This section contains possible references to other standards	The ISO 37001 has no normative references
3. Terms and definitions (p. 1)	This section contains explanations of various terms	The ISO 37001 lists 30 definitions in non-alphabetical order ^a , starting

(continued)

High-level-structure: P-D-C-A	Meaning	Content of the 37001
		with “bribery” and ending with “due diligence”
4. Context of the organization (p. 6–8)	This section sets out the purpose of the organization’s activities and identifies the stakeholders, respectively, “interested parties” that are involved	The scope of the anti-bribery management system must be clarified, stakeholders and their needs identified and the organizational environment highlighted (e.g., the geographical location and global activities, the sector in which the company operates) Establishment and implementation of a systematic risk analysis focused on corruption (bribery risk assessment). Regular risk analysis and effectiveness assessment of measures and controls must be carried out
5. Leadership (p. 8–10)	This section addresses the top management and the distribution of responsibilities and powers	The support and commitment of the top management are of great importance for a functioning management system. This section deals with the requirements for the role of the governing body and top management, the requirements for the anti-bribery policy and the

High-level-structure: P-D-C-A	Meaning	Content of the 37001
		organizational and personnel structure of this function. An independent compliance function must be appointed that is also responsible for the anti-corruption management system. The standard also provides for a possible delegation of this function to an external organization
6. Planning (p. 10–11)	The focus here is on the risk-based approach and thus the identification of opportunities and risks	Risks and opportunities, arising in relation to anti-corruption, should be identified and the objectives of the anti-corruption management system defined (“anti-bribery objectives and planning to achieve them”)
7. Support (p. 11–14)	This section focuses on the supporting processes that form the framework for the so-called core processes	Sufficient human, financial, and other resources for the implementation of the management system, e.g., training for all employees exposed to more than a low risk of corruption; staff declarations of compliance with the anti-corruption directive; documented information.

(continued)

High-level-structure: P-D-C-A	Meaning	Content of the 37001
		Performance remuneration and agreed performance targets should be designed in such a way that corruption is not encouraged
8. Operation (p. 15–18)	This section deals with the core processes	The chapter contains concrete instructions for the system: Transactions, projects, personnel, and business partners with more than a low risk of corruption require a standard due diligence process. Financial and nonfinancial controls are required (dual-control principle; transparent procurement; whistleblower system). Business associates with more than a low risk of corruption need to be monitored
9. Performance evaluation (p. 18–21)	The focus here is on monitoring and testing the effectiveness of the management system and analyzing the results	Monitoring, measurement, analysis, and evaluation of the anti-bribery management; internal audit; Review management system by anti-bribery compliance function. The results should be communicated and documented

High-level-structure: P-D-C-A	Meaning	Content of the 37001
		to the management, which provides the resources for the effective anti-corruption management on the basis of that
10. Improvement (p. 21–23)	The final section describes the continuous improvement of the system. In addition to the correct handling of nonconformity, appropriate corrective measures are described	Systematic process to prevent noncompliance or to remedy noncompliance with management system requirements. Any nonconformity shall result in an adjustment. This ensures continuous improvement of the overall system

Source: Own depiction. (Structure of the 22-page standard (37001, p. 1–22))

^aCf. ISO https://www.iso.org/sites/directives/current/consolidated/index.xhtml#_idTextAnchor454 “The arrangement of terms and definitions should preferably be listed according to the hierarchy of the concepts (i.e., systematic order). Alphabetical order is the least preferred order.”

In the annex that is 23 pages long (“Guidance on the use of this document”), examples and recommendations of how the requirements that are set out in the main text can be implemented are given. Those recommendations that can be easily identified by the modal verb “shall” completes the standard. The information in the appendix is optional and irrelevant for certification.

ISO 37001 highlights corporate culture as crucial to the success of corruption prevention (37001, VI.). For a sustainable success, compliance must be anchored in an organization’s culture, behavior, and attitudes. The standard therefore particularly emphasizes the role of the management in establishing a compliance culture (37001, 5.1.8, p. 8; see also Grueninger and Kissmehl 2021). “ISO 37001 program framework – when distilled to its essence – is composed

of the following ten elements: (1) culture, (2) governance and oversight, (3) risk assessments and due diligence, (4) policies and procedures, (5) training and communications, (6) speaking up (whistleblowing), (7) investigations and case management, (8) auditing and monitoring, (9) third-party risk management, and (10) continuous improvement. Each element is composed of detailed guidance and requirements” (Crescenzi 2018, p. 37). In addition, ISO 37001 requires companies to document their programs comprehensively.

The Way to Certification

A company might show the agreement of its operations with the requirements of ISO 37001 through a certification process. Although ISO develops standards for this certification process, it is not directly involved in it (ISO 2020c). Instead, third parties, the so-called “external certification bodies” are responsible for it.

Accreditation Process of the Certification Bodies

Each country has its own accrediting body (E.g. Accreditation Body in Germany: DAkkS; in the USA: ANAB and ANSI; the United Kingdom: UKAS), which grants certification bodies permission to certify specific ISO standards (Cherepanova 2019). Since the publication of ISO 37001 it has been criticized that the examination qualities of certifiers might vary given that the accreditation of certifying bodies is handled differently between countries (Murphy 2019, p. 11; Fox 2018; Cherepanova 2019).

With the publication of ISO 37001 in October 2016, the ISO-“Committee on conformity assessment” (CASCO) adopted ISO/IEC TS 17021-9:2016-10 (ISO/IEC 2016), which specifies the requirement profile for certifiers of anti-bribery management systems, i.e., the necessary competencies of the team of auditors. Here it was essential to strike a balance between the general audit competence for assessing management systems and the additional, specific knowledge requirements to combat corruption (Kayser 2017).

Certification bodies can apply for accreditation by demonstrating that they comply with the relevant ISO certification standards, such as ISO 17021-9. This accreditation process is not mandatory, but only recommended (Crescenzi 2018, p. 39; Fox 2018; Grant-Hart 2018).

If a certification body already has ISO/IEC TS 17021:2015 (ISO/IEC 2015) accreditation, for example, because it has audited the ISO 9001 quality management standard or the ISO 14000 environmental management standard in the past, it can go through a simplified accreditation procedure or apply for an “extension of accreditation” to its national accreditation authority. Most of the certification bodies accredited according to ISO/IEC TS 17021-9:2016 have used this procedure up till now (status: April 2019; Cherepanova 2019).

Critics complain that the relevant verification process is not very extensive and too unspecific, as the auditors’ knowledge of anti-corruption measures, their experience in corporate compliance management, and their knowledge of uncovering white-collar crime in the context of bribery does not need to be adequately documented (Cherepanova 2019). The audit practice of compliance management systems in the past has already indicated that auditors – even in auditing companies – were often inadequately trained or lacked experience (Kayser and Grueninger 2015, p. 133). Furthermore, some national accreditation bodies are not members of the International Accreditation Forum (IAF) that provides universal processes and practices for the accreditation of certification bodies.

Since some national accreditation bodies are not members of the IAF, they do not comply with the IAF requirements, but nevertheless award accreditations to certification bodies that in turn may issue ISO certificates (Cherepanova 2019). Also quality controls and inspection measures after the accreditation of certification bodies are the sole responsibility of the respective national accreditation authority (Murphy 2019, p. 12).

Certification Process

Before the certification process begins, the organization or company must implement an anti-

bribery management system. Once this is to be certified, the company should carefully select the certifier (Grant-Hart 2018; ISO 2020c; Shah 2017). In general, the certification process is limited to the parent company or headquarters of the company unless otherwise agreed with the certifier on the subject matter. Usually, each organizational unit must apply for its own certification (Crescenzi 2018, p. 40) and pay the costs by itself. The costs and the scope of the certification vary and depend on, for example, the pricing of the certification company, the size, and location of the company going to be certified.

After the contract between X and Y is signed, the preparation for the audit that can include an optional pre-audit begins. The certification audit is divided into two stages. The first stage is the document examination stage in which the certifiability of the company to be audited, usually on the location of the company’s headquarters, is determined. If the certifiability exists, the auditors agree on daily audit plans based on the size and structure of the company. In their procedure, the auditors must orient themselves on the principles of ISO 19011:2018 (ISO/TMBG 2018; Schlegel 2018, p. 13 f). At the second stage of the audit, the auditor checks the existence of the required processes and evaluates the application and implementation of the Anti-Bribery Management System. This is the initial and comprehensive audit, in which the entire management system is checked.

The requirements of ISO37001 are formulated very broadly and in general terms and hence the standard users are required to translate the requirements into plausible and internally applicable anti-bribery specifications for their operations. During the audit, the auditors verify whether all requirements have been taken into account and whether demanded documents (anti-bribery policy, code of conduct, etc.) were developed. The implementation and application in the individual organizational areas are randomly vetted and evaluated (Schlegel 2018, p. 15). In their work, the auditors check against the standard requirements. The audit team focuses solely on the scope of the relevant standard and may not audit or review any aspect of the company that do not fall within the

scope of the relevant ISO standard (Crescenzi 2018, p. 39).

The control of the management system is based on a limited sample during the period covered by the review program. For this reason, certification cannot guarantee future compliance (Shah 2017).

For the company under review, the certification audit is associated with extensive, time-consuming documentation requirements and resource-intensive audits. If no nonconformities are found, the auditors recommend the certification to the certification company following the audit. If the auditor detects a major nonconformity, which is a massive violation of ISO 37001 requirements and which restricts or completely blocks the functionality of the entire anti-bribery management system, “the organization will have three months’ time to correct them and implement the appropriate corrective measures” (Trevley 2017). Finally, the auditor recommends the certification once he has verified evidence of the organization’s correction of the major nonconformity.

The audited company receives a written report and certification logos, also known as certification marks, together with the certificate. They may be used by audited companies for internal and external communication, for example, in annual reports, on the homepage, or in e-mails. However they may not be printed on the company’s products and goods (QMS 2017).

Certifications are generally valid for 3 years. Monitoring audits must be carried out in the second and third year after the successful certification, albeit, they are limited to the examination of parts of the management system and their effective implementation in the company. After 3 years, a recertification audit in which the complete management system will be again reviewed must occur (Breit et al. 2018, p. 13).

Discussion

Reasons for Certification

Certificates help to solve problems to which the principal-agent theory in the sense of the New Institutional Economics draws attention to (cf. Jensen and Meckling 1976; Rose-Ackerman

1978): as instruments of signaling. Certificates reduce information asymmetries as the agents send signals. Signals can be in the form of a certificate issued by an independent third party or a seal of quality that certified their performance.

These signals reduce the uncertainty of the principal and thereby reduce the risk of adverse selection, increase the principal’s trust, and ultimately persuade the principal to conclude a contract. The aim of signaling is thus to prevent adverse selection and to achieve a market result that is satisfactory for both sides, the principal and the agent (cf. King et al. 2005; Terlaak and King 2006).

Certifications such as ISO 37001, which is on its way to becoming internationally recognized, can be a distinguishing feature and a competitive advantage in day-to-day business, for example, in the communication with banks and investors, with customers, and within the framework of public tendering processes. A valid certification may demonstrate that a company is committed to the prevention of corruption, does not pay bribes, and thus sends signals up- and downstream into its own supply chain. Certifications for nonprofit organizations could strengthen the trust of their stakeholders which might increase their willingness to donate. At the same time, the audit process offers companies a benchmark for assessing their own management systems, might uncover grievances, and provide impetus for improvement. A certification process might have a performance-enhancing effect within an organization, due to the positive internal stress-test in the form of setting a deadline for eliminating nonconformities and recurring surveillance audits.

Systematic anti-corruption management should prevent corporate crimes and reputation damages resulting from corruption. However, the impact of certifications on investigative authorities is strongly disputed. While supporters of third-party audits claim that ISO 37001 certifications can show investigators that a company has adopted a systematic, transparent, and serious approach to the prevention of corruption, critics point out that neither should certification be misinterpreted as panacea nor its impact exaggerated. Companies face the uncertainty whether ISO

ISO 37001 certification could lead to an exculpation or a reduction of penalties. In Germany, a majority of legal experts (prosecutors, lawyers, etc.) doubt that certification would in fact be accompanied by a possibility of release from liability (Kayser and Grueninger 2015, p. 134). Even experts who were closely involved in the development of the ISO 37001 emphasize that certification alone will certainly not – according to whatever standard – result in a disclaimer of liability (Kayser and Grueninger 2015, p. 134). In publications and lectures, courts and public prosecutors all over the world continuously stress that exculpation does not arise singularly from documents, but rather from the exemplary function of the management, the “tone from the top” (see section “Foresight”). An instrumentalization of the norm by companies that do not live up to the anti-bribery management in day-to-day business life will quickly be exposed in court by thorough investigations (Kayser and Grueninger 2015, p. 134). Prosecutors will not be influenced by the existence of ISO 31007 when investigating illegal practices and assessing the appropriateness of measures taken by a company. However, companies that have an anti-corruption management system may submit the documentation prepared for the system’s certification to proof their efforts (Volintiru et al. 2018, p. 127). At the same time, critics note that the relevant audit documents could also be used in criminal proceedings against companies (Chen 2019) and that certification users should be aware of this. This danger exists when there is a lack of integrity in the company. In contrast, ISO 37001 stresses that “a culture of integrity, transparency, openness and compliance” (37001, VI.) is critical to the effectiveness of any anti-corruption management system.

An enormous strength of the standard is to stress the role of management for compliance programs (Murphy 2019, p. 31). ISO certification does not make companies bulletproof and a certificate does not protect against corporate misconduct. It is not possible to certify that no organizational member will be involved in a bribery offence (37001, 4.4, p. 7). Only serious compliance management and an active corporate culture can exclude or at least reduce a company’s

liability. ISO 37001 is a clear, systematic, and appropriate approach to fighting corruption and managing corruption risks. Its focus on the strategic pursuit and the implementation of anti-corruption objectives corresponds to strategic planning in companies (Zentes 2017, p. 155). The risk-based approach ensures that corruption risks are countered through targeted and efficient measures (Breit et al. 2018, p. 14). A corruption risk analysis is an essential component of the standard requirements. All departments and employees that are subject to a high risk of corruption are obliged to deal with the issue of corruption. The special role and treatment of third parties is also mentioned several times in the standard (e.g., 37001, 8.5; 8.6; i.e., 13.3.2 b). The emphasis on the systematic approach helps to bundle the individual activities of compliance, operational units, audit, legal department, etc., in such a way that a uniform, coordinated, and sustainable management system exists within the company (Breit et al. 2018, p. 14). Further motives for a company to obtain ISO 37001 could be positive experiences with the advantages of other ISO management system standards. Because of the *high-level structure* of ISO the implementation of further management systems is likely to be more efficient and the establishment of an integrated management system becomes conceivable (Markowicz 2018b, p. 560).

Irrespective of certification, the requirements of ISO 37001 provide a legitimate and recognized framework for the implementation of a compliance and ethics program based on best practices (Kayser and Grueninger 2015, p. 135). For companies that do not yet have a compliance management system or an insufficient anti-corruption program, the standard can provide valuable information.

Reasons Against Certification

Despite the aforementioned advantages, the ISO standard and its certification process have also been subject to severe criticism. Instead of promoting the development of a custom-fit compliance management system and the evolution of one’s own corporate culture, there is the danger of tying up resources through overly complex

documentation and audit preparations (Kayser and Grueninger 2015, p. 133). Therefore, the costs and benefits of certification should be thoroughly evaluated in advance.

Critics of ISO 37001 see no innovation in the new standard. They criticize a profitable business with content that has been publicly accessible for years (Crescenzi 2018, p. 38; Fox 2018; La Neve 2018), for example, in publications of the British Ministry of Justice and the OECD, to which the ISO 37001 itself refers. Moreover, the standard is not a law and the fight against international corruption requires political, legislative, and judicial efforts that go far beyond the powers of a non-governmental organization. On the contrary, supporters of the norm point to the strength of the framework that summarizes existing concepts in an international consensus and by broad, recognized, and, above all, practicable access to the topic (Kayser 2017, p. 2). In addition, the detailed references in the standard are said to go far beyond the specifications of other publications and would thus provide an illustration and design of already known requirements (Crescenzi 2018 p. 38).

ISO 37001 is the only anti-corruption guideline that can only be obtained for a fee via ISO or the respective national standards body (Murphy 2019, p. 24). It is questionable whether smaller companies will decide to purchase the ISO document. In addition, the strict ISO copyright has been criticized, as it restricts the use of individual extracts from the standard for scientific purposes and “this [...] may limit open debate and discussion” (Murphy 2019, p. 24).

Finally, critics exist with regard to ISO as such. In particular with regard to its transparency and reporting.

Each country has its own ISO organization, which provides information of existing certification companies. Yet, neither does a central, international database with information of certified companies nor who has carried out the companies' certification process exist.

Even the annual ISO survey contains only incomplete information on the sectors in which the 872 companies that received ISO 37001 certification in 2019 are active. This information is

only available for 377 of the 872 valid certificates (ISO 2020b).

Some criticism is also directed at the role of the auditors. For example, it is doubted that actors who make use of quality management methods and experiences can achieve an adequate level to judge the legal-sociological behavioral patterns of compliance in a company. Finally, in contrast to a technical and procedural approach, other evaluation methods are in demand (Schefold 2017, p. 34) and acts of bribery are very diverse and multilayered worldwide (La Neve 2018). Like every certification measure, the audit of the anti-corruption system is based on the professional judgment and integrity of a few auditors. Critics deprecate a lack of transparency in the certification process, since there is a danger of a “tick-the-box” approach and the evaluation of the anti-bribery management system is mostly based on a paper review. Much depends on the skills and experiences of the auditor (Shah 2017) and it is always questionable whether the company under investigation will give the auditor access to all necessary documents and employees working at different levels of a company (Murphy 2019, p. 14).

It might be worth to invest instead on internal audits and an expansion of the legal department in order to intensify the fight against corruption. This approach could build and cultivate robust and trustworthy relationships in all business areas (La Neve 2018). Certification, on the other hand, carries the risk that managers regard it evidence that enough has been done for compliance and that further efforts are unnecessary (Murphy 2019, p. 19). Although this risk may exist, the requirements of ISO 37001 for continuous improvement mitigate it. Other compliance experts have fundamentally questioned the effectiveness of management systems by criticizing the lack of sound, empirical research that testifies the prevention of misconduct by them (Chen 2017). The lack of empirical values must be countered by the fact that ISO 37001 was published only a few years ago and that this evaluation represents a major challenge in any case (Murphy 2019, p. 9).

If one focuses on the weaknesses of the content of the standard text, one encounters the hint that

ISO 37001 does not contain the term “compliance manager”; in contrast to the content of ISO 19600 (see also Grueninger and Kissmehl 2021). ISO 37001 also does not stipulate that the person responsible for anti-corruption management must be a senior or a top manager. Many compliance experts agree that the approach of “compliance as a staff task” has proved unsuccessful in practice and that the only promising concept is “compliance as a management task” (Grueninger 2019, p. 28; Murphy 2019, p. 3 f). “A mid-level lawyer is not going to satisfy an enforcer’s expectation of a true chief ethics and compliance officer (particularly in cases where the violation involves top level people, which is often the case)” (Murphy 2019, p. 35, cf. also Grueninger and Schoettl 2017). This clear position is lacking in ISO 37001. Instead, it even allows the organization to outsource its entire compliance program (5.3.2, p. 10). With regard to this key point, ISO 37001 even deviates from its predecessor, BS 10500: 2011, that does not provide for outsourcing the entire program.

Many promoters of ISO 37001 stress its general character and its broad applicability to various types of organizations. Weaknesses can also be identified here. Statements in the text of the standard are very general and may offer companies too much room for interpretation; creating potential misunderstandings (Murphy 2019, p. 12). In addition, the bulky form of the standard is criticized. Avoidable repetitions, nested sentences, word doublings, and superfluous text lengths would lead to comprehension difficulties. It has been criticized that the appendix is only illustrative. It is unclear to the recipient why recommendations introduced in the appendix with the verb “should” have not been included into the binding standard text (e.g., 37001, A.6.3. “direct communications relationship to the governing body,” Murphy 2019, p. 39).

Geographical Distributions

Since the introduction of ISO 37001 in 2016, several organizations and companies have received ISO 37001 certification. Between

01 January and 31 December 2019, 872 ISO 37001 certifications were issued worldwide by IAF-accredited certification bodies (ISO 2020b). In the same period of time, more than 880.000 companies received ISO 9001 certificates. Most of the 37001 certificates were given to Italian (330), Mexican (57), Malaysian (44), and Spanish (43) companies. In addition, the annual report shows that ISO 37001 is preferred by larger organizations with several sites (ISO 2020b).

Several countries have already dealt with ISO 37001 and have chosen different paths: Singapore has presented a country-specific version of ISO 37001, the Singapore Standard (Martin and Tan 2017). The City of Shenzhen in China published the “Shenzhen Standard,” an anti-bribery management standard in June 2017 (Fang 2017). In Malaysia, a number of government agencies have been ISO 37001 certified (Crescenzi 2018, p. 40), in addition to those companies whose decision to certify may have been influenced by the revision of the Malaysian Anti-Corruption Act of 2009, Section 17A, which came into force in June 2020. Public prosecutors in Brazil (Odebrecht 2018) and Denmark (Atea 2018) have already recognized ISO 37001 certification in investigative proceedings to settle allegations of bribery (MacMurray 2019).

Foresight

Whether the 37001 standard will become a success story in the fight against corruption depends on various factors. On the one hand, the global awareness of the standard must increase its relevance in day-to-day business. ISO 9001 has achieved its high status, since certification according to it is often the prerequisite for establishing business relationships worldwide. The environmental management system (ISO 14001) is subject to certification pressure in certain sectors, e.g., the automotive and electrical industries (Brauweiler et al. 2015, p. 7).

In addition, the way in which nation states and their respective judiciaries will deal with ISO 37001 certification will be important. In some countries, courts and state institutions are already taking

effective compliance solutions into account when determining sanctions in favor of companies (Makowicz 2018a, p. 34). Such possibilities can be found, for example, in Great Britain (MoJ UK 2010), France (Sapin II) and Spain (Art. 31 Código Penal 2015). In associated documents, however, it is pointed out that certifications “*may not necessarily mean that a commercial organization’s bribery prevention procedures are ‘adequate’ for all purposes [...]*” (MoJ UK 2010; see also FGE 2016). In the near future it will become clear whether governments, public prosecutors’ offices, and international organizations will recognize and adapt ISO 37001. Crucial for the further dissemination of the standard will also be the continuation of consistent prosecution of bribery, so that corruption prevention pays off for companies operating with integrity (cf. Rose-Ackerman 1978).

When selecting their certification company, companies are called upon to carry out their third-party assessment carefully to eliminate the weaknesses of the accreditation process that have already been pointed out (see section “[Accreditation Process of the Certification Bodies](#)”). The ISO, in turn, could standardize the accreditation of certification bodies internationally and implement credible control mechanisms globally for quality assurance in order to increase confidence in certifications. It would be a fatal signal if it would be worth to be tested by a compliant, inexpensive certifier in order to benefit from the competitive advantage of certification and still pay bribes (Murphy 2019, p. 21). In this context, it is also worth considering whether the free choice of the certifier on the part of the companies should be restricted in the future and whether instead a neutral authority could determine the auditor, as is already the case with supplier audits. The selection could also be made randomly from a selected group of certification companies. For contrary to the selection of an auditing company, which the company can also choose freely, the certification practice suffers from the problem that, no state regulatory authority is involved for monitoring as described above (Murphy 2019, p. 17/18, see also section “[The Way to Certification](#)”).

The debate on corporate social responsibility could also promote the importance of ISO 37001.

Today, companies on the world market that violate laws or international conventions are held accountable by civil society, the media, and NGOs. They grant or withdraw companies the “licence to operate” – regardless of the existing political or legal framework (Kleinfeld and Zubrod 2016, p. 135). When formal law is weak within countries and across borders, companies play the role of global “citizens” (Rose-Ackerman 2018, p. 21) who promote good corporate values and practices.

An internal ISO development could be a critical factor for the future of ISO 37001. Standards must be reviewed every 5 years by the responsible bodies. If the contents of the standards are still up to date and relevant, their validity will be extended by another 5 years (Lüttmann and Rey 2019).

In 2014, ISO 19600:2016–12 was published as a Type B standard with guidelines for compliance management systems (Grueninger and Kissmehl 2021). The two ISO standards 19600 and 37001 originated independently of each other, since a merger of both projects was not approved by ISO (Ehnert 2015, p. 9).

Since the publication of ISO 19600, companies have increasingly asked to be certified. In response, the relevant standards committees are currently revising the ISO 19600 standard. The change will lead to a Type A standard called ISO 37301, which allows direct certification. What can be already seen from the committee’s work is that the members of the Chinese standardization committee are in particular driving the transformation of the standard forward (Lüttmann and Rey 2019). ISO 37301 is expected to be published in English in 2021 (Wuerz 2020). It remains to be seen whether this step will have an impact on the reception of ISO 37001. Although ISO 37001 contains specific provisions for managing the risk of corruption (Makowicz 2018a, p. 14), standard 37301 could prove to be more global and thus more attractive for companies.

Summary

From the perspective of game theory, the act of corruption constitutes a prisoner dilemma (Rose-

Ackerman 2018, p. 15). While individual bribes can maximize profits, a complete elimination of corruption would be beneficial for all companies. Some scholars believe “that a prisoners’ dilemma can be converted into a coordination game through dialogue, public relations, and outside pressure” (Rose-Ackerman 2018, p. 15 f; cf. Pieth 2014). Certification could be one building block in a list of corresponding measures.

ISO 37001 certification alone will not eliminate the global phenomenon of corruption. However, the standard shows that companies cannot benefit from widely ramified supply chains, on the one hand, and ignore the illegal and illegitimate activities of their business partners with regard to bribery on the other hand. Instead, companies also have a responsibility to approach their business partners and the sales intermediaries in their value chain and to require them to implement anti-bribery controls (37001, 8.5; 8.6; A.13.3.2 b).

The standard has the potential to reduce business risks and costs associated with bribery by providing a clear framework for preventing, detecting, and combating bribery. No anti-corruption program however, irrespective of how robust it might be, can prevent bribery at all times and thus fully protect the company from prosecution. Admittedly, the standard does not make this promise.

ISO 37001 is a management standard that supports companies in the fight against corruption “[...] but it will be effective only when there is a real involvement of top management [...]”. To be truly effective it is necessary to change the mindset and culture of corruption in a whole organization” (Kafel 2016, p. 223). However, the influence of politics and society on bribery should be taken into account, too. It is quite exhausting and costly for a company operating in a corrupt environment to refrain from bribery and to be “[the] only honest firm in a sea of corruption” (Rose-Ackerman 2018, p. 15 f.). ISO 37001 can nevertheless offer support in this struggle and highlight the international backing in its development process, as it is an internationally agreed standard that can be applied throughout the world in contrast to many other guides and anti-

corruption laws that are limited to specific regions and jurisdictions.

Definition

ISO 9000 has first been introduced in 1987, by the ISO Technical Committee ISO/TC 176 “Quality management and quality assurance” whose aim was to create the universal quality standard (Taormina 2019). ISO 9000 refers to the set of international quality management system standards that are meant to be implemented by organizations that tend to ensure that their goods and/or services continually meet the needs, requirements, and expectations of customers, as well as, applicable statutory and regulatory requirements (ISO 2019a). ISO 9000 standards series refers to three different quality management standards, that is – ISO 9000 – “Quality Management Systems – Fundamentals and Vocabulary” – that includes the “fundamentals and vocabulary” required for the successful implementation of an effective quality management system, ISO 9001 – “Quality Management Systems – Requirements” – which contains a set of requirements and is the only standard from the ISO 9000 series that can be certified to, and ISO 9004 “Quality Management Systems – Quality of an Organization – Guidance to Achieve Sustained Success” that consists of guidelines for the sustained success. ISO 9000

standards series can be implemented in different organizations, regardless of their size, industry, or sector (ISO 2015a). It aims at supporting the organization in achieving and maintaining the customers’ satisfaction, and gives organizations the capacity to meet new challenges and opportunities, drive sustainability objectives, and achieve sustained success (ISO 2015a).

Core Standards

ISO 9000:2015 – “Quality Management Systems – Fundamentals and Vocabulary” presents the foundation for all of the other quality management system standards, as it helps organizations of any size understand all of the “fundamentals and vocabulary” needed for the successful establishment of the effective quality management system in the organization (ISO 2015a).

ISO 9001:2015 – “Quality Management Systems – Requirements” contains the requirements for organizations that tend to ensure that their goods and services continually meet the needs, expectations, and requirements of customers, as well as, other applicable statutory and regulatory requirements (ISO 2019a). The first version of this standard – ISO 9001:2008 – was revised in 2015 to allow easier integration with other management system standards (for example, ISO 14001:2015). ISO 9001:2015 includes elements such as a stronger focus on customers and the context of the organization to fit the emerging needs of contemporary organizations (ISO 2015b). ISO 9001:2015 is the only standard from the ISO 9000 standards series that can be certified to (ISO 2019a). Accredited certification to ISO 9001:2015 provides objective evidence that an organization conforms to a set of requirements and can deliver goods and services that meet customers’ needs, requirements, and expectations (ISO 2016).

ISO 9004:2018 – “Quality Management Systems – Quality of an Organization – Guidance to Achieve Sustained Success” provides guidance for achieving sustained success (ISO 2018). ISO 9004:2018 is not a certification standard, but it provides a framework for organizations of any

size to assess their maturity level, and explore all the opportunities for improvement (Naden 2017).

Key Changes Between ISO 9001:2008 and ISO 9001:2015

Aiming to create consistency between all global management system standards, ISO created a new version of ISO 9001:2015 following the Annex L (formerly known as Annex SL). The focus of the new standard is on the organizational context and the need for the support of the top management for the development of an effective quality management system; much more attention is being paid to “processes and process approach, and less on documentation”; the risk-based thinking was introduced to “add some systematic evaluation” to the current and future, actual or potential risks, thus making the organizational processes “more robust”; special attention is being paid to “the change management and knowledge management,” and “the continual improvement” was replaced by “the concept of improvement,” thus addressing “the change to the way management thinks” (see Fonseca 2016, Fonseca and Domingues 2017).

Principles

The seven quality management principles were established by experts gathered around the ISO/TC 176, and they are listed as follows (ISO 2015b):

- QMP 1 – Customer Focus
- QMP 2 – Leadership
- QMP 3 – Engagement of People
- QMP 4 – Process Approach
- QMP 5 – Improvement
- QMP 6 – Evidence-Based Decision-Making
- QMP 7 – Relationship Management

These principles were not given in the priority order. According to ISO (2015b) – “for each quality management principle, there is a *statement* describing each principle, a *rationale* explaining

why the organization should address each principle, *key benefits* attributed to each principle, and set of *possible actions* that an organization can take in applying each principle” (ISO 2015b).

Concepts

Process Approach

Organizing its processes to function as a part of an integrated system allows organizations to plan, control, ensure, and improve their quality management system (ISO 2017b). The process approach helps organizations to manage their processes and activities to improve their organizational performance (ISO 2015b). The sequence of actions was developed to provide examples of how the organization may choose to implement this approach to the whole system, as well as, its processes and activities – and is available in “Guidance on the concept, content, and use of the process approach for management systems” (ISO 2017a). Figure showing “a schematic representation of any process and an interaction of its elements” can be found at the ISO platform (see ISO 2020).

Plan-Do-Check-Act (PDCA) Cycle

Planning, within **PDCA**, stands for setting goals, objectives, and targets for processes and its activities, determining all the resources necessary for achieving these goals, as well as all the potential risks, and opportunities for improvement that can occur during this process (ISO 2015b). **Doing** means actually applying what was planned (ISO 2015b). **Checking** refers to managing processes and activities and their results in order to compare them with planned goals (ISO 2015b). **Acting** (if applicable) stands for improving organizational performance (ISO 2015b). Figure showing the structure of ISO 9001:2015 in relation to the PDCA cycle can be found at the ISO platform (see ISO 2020).

Risk-Based Thinking

The latest version of ISO 9001:2015 addresses risk-based thinking as an essential component of the system which can help organizations to identify all the potential risks that can occur during the

process (ISO 2015b). As the system tends to prevent or reduce discovered nonconformities, risk-based thinking adds value and offers opportunities for improvement (ISO 2017b).

Sustainable Development Goals (SDGs)

In 2015, the United Nations (UN) set out 17 Sustainable Development Goals (SDGs), which were then accepted by all UN Member States, as a part of the 2030 Agenda (UN 2019). ISO 9000 standards series can be an essential component of the achievement of the SDGs. Given that standards are a key element of “a new, sustainable world” (ISO 2014) – there is a belief that all stakeholders and interested parties involved in or responsible for standardization in formal and informal organizations for standardization, professional or industrial associations, consortia, fora, governments and governmental organizations, and educational establishments shall make a significant contribution to the achievement of the sustained success (ISO 2014).

According to ISO (2019b), ISO 9001:2015 contributes to the following SDGs:

- SDGs [1] – No Poverty
- SDGs [9] – Industry, Innovation, and Infrastructure
- SDGs [12] – Responsible Consumption and Production
- SDGs [14] – Life Below Water

According to ISO (2019c), ISO 9004:2018 contributes to the following SDGs:

- SDGs [8] – Decent Work and Economic Growth
- SDGs [9] – Industry, Innovation, and Infrastructure
- SDGs [10] – Reduced Inequalities

The successful development of an effective quality management system can be beneficial for most organizations, as it gives them the opportunity to drive sustainability objectives and face new challenges all over the world.

Summary

ISO 9000 refers to the set of international quality management system standards that can be implemented by all organizations that tend to ensure that their goods and services continually meet the needs, requirements, and expectations of customers, as well as, applicable statutory and regulatory requirements. ISO 9000:2015 “Quality Management Systems – Fundamentals and Vocabulary” presents the foundation for all other quality management system standards. ISO 9001:2015 is the only standard from the ISO 9000 standards series that can be certified to – certification to ISO 9001:2015 “Quality Management Systems – Requirements” provides evidence that organizations conform to a set of requirements and deliver goods and services that meet customers’ needs, requirements, and expectations, as well as, applicable statutory and regulatory requirements. ISO 9004:2018 “Quality Management Systems – Quality of an Organization – Guidance to Achieve Sustained Success” is not a certification standard – rather, it provides a framework for organizations of any size to assess their maturity level, and explore all the opportunities for improvement. The successful development of the quality management system can be beneficial for most contemporary organizations, as it gives them the opportunity to drive sustainability objectives and face new challenges all over the world.

Definition

This article discusses the ISO 19600, an international cross-industry standard that contains

directives for the use of compliance management systems. The standard is designed as a guideline and is based on the principles of good governance, proportionality, transparency, and sustainability. It covers all forms of corporate and organizational structures and aims to support managers and employees in avoiding unethical conduct. The authors describe the principles of the ISO 19600 standard and in this context examine in more detail the three core elements that form a successful compliance management system: a high-level structure, a risk-based approach, and a plan-do-check-act model. In addition, compliance culture and the role of management are discussed.

Introduction

The ISO 19600 is an international set of rules that contains directives for the use of compliance management systems. The cross-industry standard can be regarded as a guideline for setting up, developing, implementing, evaluating, maintaining, and improving an adequate and effective compliance management system (CMS) within an organization.

This universal standard is based on the principles of good governance, proportionality, transparency, and sustainability (ISO 19600:2014, Number 1) and is flexible regarding the handling (Fissenewert 2015, p. 199). The directives developed cover all forms of corporate and organizational structures.

The scope of the application depends on the size, structure, type, and complexity of the organization. It can thus be used to target not only large companies, but also medium-sized businesses, as well as foundations, associations, federations, and governmental agencies – both in the private and public sectors.

The purpose of the standard is to support managers and employees in avoiding improper conduct. This is achieved by evaluating the effectiveness of compliance measures through internal and external communication, continuous process improvements, and establishing a sustainable compliance culture (Scheffold 2015, p. 10).

The ISO 19600 is published as a Type-B standard, whereas Type-A standards (i.e., ISO 37001) contain requirements against which an organization can claim conformance and therefore is approved for certification. ISO 19600 provides guidance and supporting information and intentionally consists of recommendations (shoulds) and not explicit mandatory requirements (musts).

The ISO 19600 thus provides an overview of measures of basic standards and recommendations that should be taken into consideration when introducing a CMS, such as:

- The assessment of the business environment and compliance risks
- Leadership with different roles and responsibilities within an organization
- Systematic management and control mechanisms
- Training and communication
- Monitoring, internal audits, and incident response

It is designed as a guideline and supplements other international and national standards. At the same time, however, it can also serve as a framework in countries which either do not yet have national standards or in which no international standards have yet been established.

History

International companies have been dealing with a number of different national and international requirements over the past years which can be derived from laws or voluntary standards (e.g., the UK Bribery Act of 2010, the US Sentencing Guidelines for Organizations, the German IDW PS 980, the ComplianceProgrammMonitor^{ZfW}, or the KICG CMS-Guidance 2014). This has led to the wish for a certain standardization of these requirements, as well as making it easier for these companies to set up and implement such management systems. This focus on standardization is understandable, in particular due to the sufficient level of awareness of basic CMS

elements. The International Organization for Standardization (ISO), in general a more technically oriented standards organization, most likely wanted to accommodate this desire. If one takes a closer look at the standards, the technical background of the organization is indeed noticeable. Typically for an ISO standard, ISO 19600 was developed and revised by committees consisting of different expert working groups.

In June 2012, ISO member Australia made a proposal to start developing an ISO standard for compliance programs based on its own national standard AS 8306 from 2006. This proposal was accepted by the ISO members, and a project committee including experts from 11 countries was set up to develop the standard. Three global meetings took place between April 2013 and July 2014 (in Sydney, Paris, and Vienna). The experts discussed more than 400 comments from over 20 countries with observation status according to the consensus principle, and a 33-page document containing 50 clauses based on these discussions was published in December, 2014.

Principles of the Standard

The standard is essentially based on three different models, which are combined to form one compliance management system. This system includes: (1) a risk management system using a risk-based approach (see ISO 31000), (2) a high-level structure (HLS) which is organized like other management systems, so that the recommendations arising from the standard can be directly integrated into existing management systems, and (3) the plan-do-check-act model which is oriented towards a continuous improvement process.

High-Level Structure

A typical feature of the ISO management standard is the high-level structure (HLS). This enables organizations that have already implemented other ISO standards to adopt the existing structures and add additional corresponding compliance functionalities. However, the standard explicitly states that the recommendations can

also be implemented in organizations that have not yet set up this type of management system.

The HLS includes the following elements:

Elements of HLS	Guidance on compliance in ISO 19600
Scope	• Guidance for establishing, developing, evaluating, maintaining, and improving an effective and responsive CMS • Applicability to all types of organizations – extent of application depends on the size, structure, nature, and complexity of the organization • Based on the principles of good governance, flexibility, proportionality, transparency, and sustainability
Normative references	None
Terms and definition	In the sense of a link to previous, above all technically understood management systems, ISO 19600 first gives an overview of the terms to be defined, for example: • Compliance: meeting all the organization's compliance obligations, which arise from mandatory requirements, such as applicable laws and regulations, or voluntary commitments such as organizational and industry standards, contractual relationships, principles of good governance, and community and ethical standards • Compliance culture: the values, ethics, and beliefs that exist throughout an organization and in the behavior and attitude of people working for it which interact with the organization's structures and control systems to produce behavioral norms that are conducive to compliance outcomes
Context of the organization	• Analysis of the environment in which the organization operates (context, issues, stakeholders, and their requirements, needs, and expectations) • Scope of the compliance management system • Identification of compliance obligations • Assessment of the compliance risks

(continued)

Elements of HLS	Guidance on compliance in ISO 19600
Leadership	• Policy, commitment, and leading by example • Roles, responsibilities, and authorities with respect to compliance for the board, top and line management, employees, and an independent compliance officer
Planning	• Planning of measures to control compliance risks • Establishing compliance objectives
Support	• Awareness, competence, and training compliance • Behavior and culture • Communication and documentation
Operation	• Implementation of controls for compliance (technical, procedural, directing the attitude and behavior of personnel)
Performance evaluation	• Monitoring of compliance, application of indicators • Analysis of information and reporting of results (internal and external) • Internal audit and management review
Improvement	• Actions on noncompliance with requirements and escalation to higher management levels when necessary • Corrective action • Improvement activities

Risk-Based Approach

For a long time, compliance has been in the shadow of risk management. The new ISO 19600, however, is based on a risk-based approach in the spirit of ISO 31000 (ISO standard for risk management) and thus serves to manage compliance risks. This is based on a systematic approach that provides organizations with valuable information about changing framework conditions. Risks are identified, analyzed, and evaluated in order to determine compliance requirements and establish controls. Organizations can then take measures to counteract the biggest compliance risks, weighted by their priority. According to this approach, companies first determine a responsible person (e.g., at the management level or an appointed employee), which

is followed by a three-step process consisting of (1) risk identification, (2) risk assessment, and (3) risk management. In order to concentrate management outlays and controls on the biggest compliance risks, the first step is to identify the specific risks, i.e., to identify them as comprehensively as possible, based on the most current information. An organization must decide which of its stakeholders' requirements, needs, and expectations are obligatory for the organization and must therefore be met. The term compliance has deliberately been expanded in this standard and goes beyond complying with relevant laws. In addition to obligatory compliance obligations, the ISO 19600 also includes obligations that an organization would like to fulfill, such as compliance with voluntary principles, industry standards, or agreements with nongovernmental organizations.

The starting point here is the question of the risk involved in not considering the specific needs of stakeholders as a compliance obligation. This is followed by a risk assessment, which is calculated by multiplying the probability of the occurrence of a risk by the potential loss. Concrete management efforts then focus on risk management, which includes measures to prevent, reduce, limit, and transfer risk, as well as procedures designed to monitor and evaluate the effectiveness of risk management. The risk-based approach involves bringing in experts with the sensitivity to be able to identify potential future sources of risk, as well as documenting the risks identified in the process and justifying the selection of a specific risk treatment.

Plan-Do-Check-Act Model

The idea behind the PDCA cycle is putting employees who work on site and have precise knowledge of the workplace situation at the center of planning. This then serves the system of continuous improvement. The cycle essentially consists of four management functions:

- **Plan (Develop):** The process is planned before the actual implementation and includes the identification of improvement potentials, the analysis of the actual situation, and the development of a new concept.

- Do (Implement): This is followed by an initial test phase as well as practically optimizing the concept using simple means that can quickly lead to a desired outcome.
- Check (Evaluate): This involves reviewing the processes and results initiated in the first tests and, if necessary, releasing for implementation and initiating as new standards on a broad front.
- Act (Maintain): In this phase, the new standard is introduced on a broad basis and regularly checked for compliance.

The model described above basically aligns with other management systems, is based on the

continual improvement principle (plan, do, check, and act), and consists of two phases:

1. The early phase (establish) involves setting up the system and is intended for defining goals and areas of application for the compliance management system. This can be used as a basis for defining the company's compliance policy.
2. The late phase (improve) is the risk-based operation of the system according to the PDCA cycle and includes assigning responsibilities and establishing the CMS management system (Fig. 1).

ISO19600 Compliance Management Systems, Fig. 1 Visualisation of the compliance management system (ISO 19600:2014, p. v.)

Proportionality, Flexibility, and Good Governance

An important principle of ISO 19600 is proportionality: A CMS should be proportionate, meaning that processes, structures, and measures should be comparable in scale to the defined objectives and not overly ambitious and outsized, especially in view of scarce resources.

Small- and medium-sized enterprises in particular would therefore not necessarily be forced to allocate additional personnel for this purpose. Instead of having its own compliance department or designating a compliance officer, companies can – depending on the type, size, and organization – utilize existing structures, such as an interdisciplinary committee of persons which could act as an interface to deal with and channel individual compliance issues (Makowicz and Stadelmaier 2015, p. 90). The standard can be applied to various corporate and organizational structures based on the principle of flexibility. The standard recommends an application according to the size, structure, nature, and complexity of the organization. The ISO 19600 defines good governance as having direct access to company management, being completely independent, and having the appropriate resources available. These should always be considered in terms of the principles of proportionality and flexibility.

Compliance Culture

The core of the guideline is a compliance culture, which decisively shapes how well compliance measures are accepted within companies, and is therefore integral for the success of a compliance management system. The ISO 19600 defines compliance culture as the values, ethical standards, and convictions that exist within organizations, interact with their structures and control systems, and generate behavioral norms that promote compliance outcomes. Compliance culture is often mentioned in the standard, described as the “tone from the top,” the goal of compliance training or sensitizing board members, and as the objective of compliance monitoring. The role of

management in establishing such a culture is particularly emphasized.

The concept of a compliance culture must be highlighted at this point. This culture should not only be understood as the mere willingness to behave in accordance with rules and the extent to which rule violations are violated, but is also intended to encompass areas in which no formalized rules or behavioral guidelines exist (Kleinfeld and Kettler 2017, p. 88). Company culture begins with the founding of the organization, and is characterized by a complex process of social integration involving the members of the organization – which per se makes each corporate culture unique (Fichtner 2008, p. 104).

There are three basic levels of culture:

1. Observable artifacts
2. Values and norms
3. Basic assumptions

Artifacts are the first obvious manifestations of company culture that one perceives and experiences when entering the premises of an organization – visible structures and processes of an organization that are easy to observe but difficult to decipher. These are visible and audible behavioral patterns, such as the office layout and interior design, attire, the way employees interact with one another, as well as physical manifestations such as documents or products, the organizational structure, and working hours (Schein 1990, p. 115). In the area of ethics, this level can include formal codes of conduct or public declarations on ethical values. However, the mere existence of an ethics program does not mean that it is being effectively implemented and anchored in the organization (see Kaptein and Schwartz 2008). As mentioned above, the level of artifacts is the easiest to grasp, because it consists merely of describing the environment and existing patterns of behavior. However, this level is very difficult to comprehend because, beyond this directly observable level, the underlying logic of a group's behavior remains unclear (Huhtala 2013, p. 12).

Values are part of the moral culture in all societies and help us analyze why the members of an organization behave the way they do. These

values are a benchmark for decisions and actions (Grüninger 2019, p. 52) and express what a society values (Wieland 2004, p. 13). In addition to the normative orientation function that guides behavior, values constitutively lend an organization its identity, shape the patterns of perception within the organization and its members, and also have an integrative, community-building function, provided that they can be anchored in the corporate culture. In addition to moral values, the value set of a company also includes performance, communication, and cooperation values that must be individually defined and described by the company. However, these values often represent only the expressed, “weakened” side of the culture, while the underlying reasons for typical behavior remain unconscious. The management of values can be seen as a significant tool to shape compliance culture within organizations (for a deeper understanding on the impact of value management see Wieland and Grüninger 2000, 2003).

In order to truly understand a culture and better grasp the values and visible behavior of the group, it is essential to address the underlying assumptions, which are typically unconscious, but which actually determine how group members perceive, think, and feel, and are therefore seen as self-evident by their members (Schein 1984, p. 4). These assumptions are answers that are learned, created, discovered, or developed by a particular group about how they learn to deal with their problems of external adaptation and internal integration, and thus serve as a starting point for values and behaviors. They have worked well enough to be considered valid, and are therefore taught to new members as the right way to perceive, think, and feel about certain problems (Schein 1990, p. 111). From an ethical point of view, the basic assumptions are deeper than the values mentioned and may even contradict the formal norms. For example, an organization may have a formal code of conduct and superficially implemented ethical values, while fundamental assumptions actually only value reaching business targets at any price without regard to ethical issues (Falkenberg and Herremans 1995, p. 135). These assumptions are therefore very powerful

because they are less debatable and less obviously conscious than the values they represent.

Schein’s (1984) three-stage model can be expanded to include an additional level – the organizational atmosphere (Glock 2018, p. 225), which is displayed in Fig. 2 below. It contains the typical way members of an organization perceive the internal situation and thus how they view structural aspects as well as organizational conditions. Here the subjective quality of working together – i.e., the “mood” in the company – is taken into consideration. This structural and emotional component on the one hand influences behavior in the organization, and is on the other hand influenced itself by the values of organizational characteristics (Rosenstiel and Nerdinger 2011, p. 61).

Compliance does not work without a supportive corporate culture, because the culture in an organization has a great influence on the degree of behavior based on moral of integrity within companies. This culture can motivate employees to behave ethically, and thus plays an important

ISO19600 Compliance Management Systems, Fig. 2 The levels of culture and their interaction (2). (Own figure based on Glock 2018, p. 225)

role in reducing human risks in compliance management. A truly functioning CMS can only be implemented by imparting values. Only introducing a static CMS might lead to misunderstandings and to employees' rejecting the CMS. Merely imposing prohibitions will logically lead to a low level of acceptance for compliance management (Fissenewert 2015, p. 203), because people need an attitude upon which they can and want to orient themselves. This attitude is reflected in a corporate culture that is oriented towards preventive measures, where the purpose is comprehensible and acceptable for employees, and to which people can – and want to – ultimately orient themselves. The goal is a company atmosphere that reaches the minds and hearts of all employees and does not allow unethical behavior in the first place. The behavior of managers is decisive here – compliance must therefore be understood as a “leadership task” (for a deeper understanding, see Grüninger and Schöttl 2017).

Compliance Management as a Matter of Leadership

The ISO 19600 attaches importance to the different roles, responsibilities, and responsibilities within the company and assigns a decisive role to the company management (executive board and supervisory bodies). First, management must make the decision to implement a compliance management system, then define the objectives and framework of the CMS and provide the appropriate resources. The effect of modeling within companies is very important. If management is committed to clean, legally compliant business practices and thus to preventing and punishing illegal practices, and if it lives up to this commitment, this then establishes an important prerequisite for a compliance management system to work.

The management style of top executives and the personnel management style of every manager in a company play an essential structural and cultural role in the emergence and prevention of unethical actions in companies. This is done by setting targets and in particular by manager's orientation towards moral principles and values

(Wieland 2008, p. 162). Above all, managers have a huge influence on their employees, because they trigger psychological adjustment processes through their role as models. Employees imitate the behavior of their superiors or role models via observational learning, imitation, and ultimately identification with the managers themselves (Brown et al. 2005, p. 119).

Managers' serious self-commitment and credible commitment to corporate values and rules as well as their communication play a very important role in this context. This is often referred to as “Tone of the Top” and “Tone of the Middle” in the literature. The fact that this commitment to ethical action must not only be reflected in verbal communication and written documents but must really be “lived” mirrors what we know from basic research on human communication. Modeling consistent behavior in accordance with company guidelines and, in particular, reaching employees in terms of internalizing desired norms and values can lead to an increase in integrity and compliance within the company (Kaptein and van Dalen 2010, p. 102). The same applies to agreeing on balanced goals, and taking the form and means of achieving targets into consideration when later evaluating achievements (Mayer et al. 2009, p. 7).

Rewarding exemplary behavior and introducing disciplinary measures for misconduct in a careless manner pose great dangers with regard to unethical employee behavior. When companies make unclear and ambiguous statements, avoid sanctioning, or even embellish unethical behavior by managers, this creates space for interpretation with regard to the priority of values and rules. An additional potential risk of promoting unethical behavior can be caused by the pressure perceived by an employee resulting from the superior/subordinate relationship with their manager. Overly optimistic target agreements and invitingly designed economic compensation models increase the risk of the impression that the given targets can only be achieved via unfair means. However, managers' behavior in itself also has the potential to systematically promote unethical behavior, for example, when employees feel unfairly treated. Another risk of unethical managerial behavior that is closely linked to the

organizational hierarchy structure is “management override.” This involves senior managers in a company deliberately overriding internal control and prevention mechanisms with their know-how, skills, and access.

Employees in organizations characterized by a weak ethical management culture, particularly with regard to a lack of sense of responsibility and an inappropriate role model function among managers, are 3.6 times more likely to engage in unethical behavior. This was the result of a study involving more than 5000 employees in the USA (Ethics and Compliance Initiative 2018, p. 9). Further findings confirm the theses listed above. The willingness of employees to engage in unethical behavior increases by a factor of four in organizations in which ethical behavior remains unrewarded and is not considered when performance goals are evaluated.

Further studies have shown that leadership behavior in organizations is the key factor in a company’s ethical culture (Pucic 2015, p. 655; Ethics & Compliance Initiative 2018, p. 13). For example, employees who agree that their supervisors regularly talk about the importance of ethical behavior are nearly 12 times more convinced that their organization encourages them to comment on observed problems and misconduct.

A study involving 553 German business executives from all company sizes, sectors, and hierarchical levels came to the conclusion that the most common reason for management culture changes in a company is personnel changes in top management (Cisik 2016, p. 9). Developing current managers through training and coaching is one of the most frequently used measures, followed by recruiting new middle managers (second place), formulating a management model (third place), and firing older managers (fourth place). Other measures mentioned include punishing or rewarding poor or strong leadership (11th and 12th place).

Summary

Especially for small- and medium-sized companies, ISO 19600 offers the opportunity to address the topic of compliance in a structural manner.

The existing high-level structure allows a straightforward implementation, especially if further management standards (such as, for example, ISO 9001 with regard to quality management and ISO 31000 with regard to risk management) already exist in the company.

Similar to ISO 26000 (see chapter ► [“ISO 26000 Standard”](#)), ISO 19600 has the characteristic of a guideline and is not designed as a mandatory requirement. The decision not to publish a Type-A guidance document similar to the ISO37001 (see chapter ► [“ISO 26000 Standard”](#)) was made to offer more flexibility when designing a CMS.

It should be noted, however, that implementing a CMS according to ISO 19600 is generally recommended as it shows that an organization takes active measures to ensure compliance, yet by no means provides complete and all-embracing protection against unethical behavior. A management system can only be as effective as the information fed into it. And in the final analysis, this information only provides a glimpse of the current situation.

If companies truly want to deal with the constantly emerging risks in a responsible manner, compliance must be viewed as a management task. This can only succeed if business leaders and executives become aware that both the culture and the leadership in companies influence people and are also influenced by people. Compliance as a management task means committing to the principle of integrity and consistently modeling ethical behavior.

Issue Management: A Typology of Approaches

Scott T. Davis
College of Business, Rikkyo University,
Tokyo, Japan

Definition

Issue management in business has developed over time from its origins in the 1960s and 1970s from

being primarily a reactive response to perceived environmental threats to business interests to a proactive process that is integrated into a business's strategic planning. This development can be explained as the emergence of three approaches to issue management distinguishable according to the archetype of governance upon which they are based – specifically hierarchical, market, and network-based approaches. Hierarchy is based on individual interests, specific knowledge, and planning, whereas market is based on multiple interests, nonspecific knowledge, and requirements for coordination, and network is based on collective interests, intangible knowledge, and the mode of coordination.

Introduction

Issue management – specifically the identification and management of social issues related to the planning and implementation of business – has a long history. As a concept, issue management lies at the heart of any debate regarding the social role, expectations, and value of business. Many theories and frameworks for identifying and managing issues have been developed. The development of these theories and frameworks of issue management has not been sequential, rather the growth of the field has seen the development of a number of different approaches each based upon a different concern.

This entry presents a typology of the representative theories and frameworks of issue management drawing on a number of disciplines including crisis management, strategic management, public relations, and corporate social responsibility wherein it is considered a key component. These theories and frameworks of issue management are grouped into three ideal types comprising of three approaches to issue management each aligning with one of the three models of governance: hierarchical, market, and network. The objective here is to understand and explore the meaning of theories and frameworks of issue management as forms of governance.

History of Concept

Theories and frameworks of issue management that were initially developed as part of the discipline of strategic planning in the mid-1900s continue to be applied today as an integral part of the practice of strategic management.

The term issue management in its current usage first appears in the 1960s and stems from the pre-existing fields of forecasting and future studies (Fahey and King 1977; Fahey et al. 1981). The concept received attention during this time, particularly in the USA, as business environments underwent rapid change and firms were faced with challenges including demands for environmental protection by banning the use of aerosols and the promotion of human rights for women (Wartick and Rude 1986, p. 125). Characterized as a time of turbulence by Heath, the 1960s and 1970s witnessed conflict between firms and public policy initiatives as the influence of activists became a significant factor for business (Heath 2002b, p. 206). In the face of activists calling for stricter governmental regulation of business, firms developed issue management in order to detect and respond to emerging threats (Heath 2002a, p. 209).

Accordingly, effective issue management came to be measured in terms of its efficacy in minimizing external threats and surprises (Wartick and Rude 1986, p. 126). These early formulations of issue management were therefore largely reactive, dealing with the effects rather than the causes of social issues (Buchholz 1982). Since these early beginnings social, political, and environmental changes have continued to influence firms and shape public perceptions of the role and responsibilities of corporations. The concept of issue management has subsequently been developed as a function of strategic management whereby firms practice issues management as a part of, and not simply in addition to, their strategic processes (Heath 2002b, p. 207). In the language of Wartick and Rude, issue management thereby changes from being a process for firefighting to one of fire prevention (Wartick and Rude 1986, p. 127).

Different approaches continue to be developed recently such as those aimed to facilitate analysis

and evaluation of the social performance of firms. A review of the theories and frameworks of issue management offers the opportunity to explore the development of social thought relating to business. More recently, growing awareness that firms as legal entities operate on the basis of a social license has led to the development of approaches to issue management that emphasize the need to work with social actors towards the common good rather than narrowly defined self-interest (Heath 2002b, p. 207).

Three Approaches to Management Based Upon Models of Governance

Issue management has been defined as a three-staged process whereby firms seek to identify, evaluate, and respond to environmental factors, which may influence their activities in order to avoid surprises and facilitate the effective utilization of their resources (Wartick and Rude 1986, p. 124). Issue management can be reactive, focusing on social and political issues that may impinge on its activities in the future (Johnson 1983, p. 22; Clark et al. 2017, p. 1140), or proactive and seek instead to contribute to the cocreation of desirable futures.

Issues management can be understood to be a process whereby actors seek to establish governance over matters, which need to be addressed. Governance is therefore integral to issue management. As such, issue management is shaped by the model of governance applied in the situation wherein issues are identified and managed. Different approaches to issue management can be defined according to the archetype of governance upon which it is based.

Various conceptualizations of the means by which organizations establish governance over their relationship with other organizations exist including “styles of governance” (Meuleman 2008, p. 12), “modes of governance” (Boutilier 2011), and “models of social order” (Streeck and Schmitter 1985, p. 119). All three of these conceptualizations identify three archetypes of governance: hierarchies, markets, and networks. These approaches can be identified and contrasted

Issue Management: A Typology of Approaches, Table 1 Characteristics of approaches to issues management by governance model

	Hierarchy	Market	Network
Identity and interests	Individual	Multiple	Collective
Knowledge	Specific knowledge	Nonspecific knowledge	Intangible
Emergence (“project or process”)	Application of fixed rules and procedures	Negotiation of rules	Ongoing rule making
Resource utilization	Control	Coordination	Integration
Expression of power	Control	Dispersed competition	Spontaneous solidarity
Issue management approach	Strategic	Transactional	Transformational

Source: Author

in terms of a number of characterizing factors including: interests, type of knowledge, planning, requirements for, and mode of coordination as indicated in Table 1.

Interests: Individual, Multiple, or Collective

Streeck and Schmitter characterize these three archetypes as constituting contrasting approaches to the management and expression of different identities and interests. Streeck and Schmitter contend that bureaucracy, markets, and communities are defined by the central institution that “embodies (and enforces) their respective and distinctive guiding principles” (Streeck and Schmitter 1985, p. 119).

Bureaucracies seek to maintain stability and predictability by promoting the imposition of “agreed upon procedures and regulations” based upon the public interest in order to protect “all actors from domination by external actors and in affording equitable and predictable treatment to all” (Streeck and Schmitter 1985, p. 121). Markets are explained as mechanisms to give voice to participants within a free and competitive communication forum and thereby create the accountability needed to legitimate the attainment of

economic prosperity (Streeck and Schmitter 1985, p. 121). Markets therefore legitimate relationships by facilitating the equal access to opportunities by the freedom to compete in the pursuit of interests. By contrast, communities (networks) are based on the award of recognition and esteem for leaders in exchange for the satisfaction of “mutual needs for a shared affective existence and a distinctive collective identity” of its members (Streeck and Schmitter 1985, p. 121). The mutual satisfaction of needs comes therefore by the coordinated participation in a collective identity of distinctive individual entities.

In each case, the objective of the central institution is to seek to minimize risk by maximizing predictability. For bureaucracies, issues therefore become potential threats to a planned order, for markets a point of competition over legitimacy, while within communities they can become opportunities to change and develop relationships within the collective.

Type of Knowledge Defining Relationships

Boutilier argues that the mode of governance implemented is influenced by the nature of knowledge being coordinated through relationships. For Boutilier, organizations with high dependence on specifiable knowledge tend to employ “prescribed processing routines” such as contracts to coordinate activity:

Hierarchies are typically used when transactions require more specific knowledge, equipment, and coordination. Hierarchies legitimize their governance through employment relationships and contracts. Communication among the actors takes place according to prescribed processing routines. (Boutilier 2011)

In contrast, interactions that involve little or no specific knowledge can be effectively coordinated as transactions managed as open, price-based exchanges. Boutilier further notes that:

Markets are used more when transactions do not require any specific knowledge, materials, or coordination. Property rights legitimize market governance, and the actors send signals via prices

(i.e., offers, bids, and settlements). Buying gasoline is a pure market transaction. No special knowledge or equipment is required to switch from one gas station to another. (Boutilier 2011)

Interactions involving the exchanges of intangible assets are best coordinated by networks due to the difficulty involved in defining and valuing them (Boutilier 2011).

Planning or Process Orientation

Meuleman has characterized hierarchical governance as emphasizing management in terms of carefully planned projects with contractually defined roles and clear allocations of authority (Meuleman 2008, p. 25). This contrasts with networks that are instances of process management defined by relationships sustained by mutual dependence, ongoing rule-making, complex policy, in addition to requiring active risk reduction and conflict management (Meuleman 2008, p. 33).

Resource Access and Utilization

Powell has explained the utility of hierarchical forms of organization in terms of their enabling the high levels of accountability and transparency necessary for the deployment of large volumes of resources for mass production in “high volume, high speed operations” within situations with relatively little change (Powell 1990, p. 303). However, where the prevailing need is for resources that are standardized, commoditized, and exchanged upon the basis of quality and price, there is little or no need to depend on others. Powell defines markets as a: “form of noncoercive organization, they have coordinating but not integrative effects” (Powell 1990, p. 302). Markets therefore flourish where “individually self-interested, noncooperative, unconstrained social interaction” best serves the purposes of the actors (Powell 1990, p. 302).

Networks, by contrast, consist of: “individuals engaged in reciprocal, preferential, mutually supportive actions” (Powell 1990, p. 303). Requiring

associations that are closer than the discreet transactions characterizing the market, yet more dynamic than those of hierarchies, networks enable an effective “pooling of resources” (Powell 1990, p. 303).

Power and Control

In essence, governance models are different forms of interactions between entities. Meuleman defines governance styles as the “process of decision making and implementation, including the manner in which the organizations involved relate to each other” (Meuleman 2008, p. 12). It is implicit therefore that power and control are fundamental dimensions to any consideration of governance styles.

Streeck and Schmitter have characterized these three forms of governance as relationships of power whereby communities and networks are understood as instances of “spontaneous solidarity,” markets as “dispersed competition,” and bureaucracies as embodiments of “hierarchical control” (Streeck and Schmitter 1985, p. 119).

Three Approaches to Issue Management

The mode of governance has shifted over time. Meuleman argues that public administration in Western nations has shifted from a primary focus on hierarchy since the Second World War until the 1980s, to subsequently include market mechanisms and more recently to include networks from the 1990s. Meuleman characterizes this shift as one which “enriched the range of possible steering, coordination and organisation interventions” available for public administration (Meuleman 2008, p. 1). Streeck and Schmitter contend that at present: “almost everyone would concede that modern societies, politics or economies can only be analysed in terms of some mix of [governance models]” (Streeck and Schmitter 1985, p. 119).

The outcome of this shift has been the development of three approaches to issue management: a

hierarchical approach based upon strategy, a transactional approach based upon markets, and a transformational approach based upon networks (see entries on ► [“Issue Management: The Strategic Approach,”](#) ► [“Issue Management: Market Approach,”](#) and ► [“Issue Management: The Network Approach”](#)). Issue management involves the identification and management of social issues related to the planning and implementation of business. Several theories and frameworks of issue management have been developed over time, each based on different concerns. These approaches can be ordered into three ideal types, each aligning with one of three models of governance: hierarchical, market, and network. These approaches are characterized by various factors, including interests, knowledge, planning, coordination, and more. By exploring the development of social thought relating to business, it is evident that issue management has evolved to become a function of strategic management, shifting from being a process for firefighting to one of fire prevention. The recent focus on social license has further led to the development of approaches to issue management that emphasize the need to work with social actors towards the common good.

Summary

Issue management involves the identification and management of social issues related to the planning and implementation of business. Several theories and frameworks of issue management have been developed over time, each based on different concerns. These approaches can be ordered into three ideal types, each aligning with one of three models of governance: hierarchical, market, and network. These approaches are characterized by various factors, including interests, knowledge, planning, coordination, and more. By exploring the development of social thought relating to business, it is evident that issue management has evolved to become a function of strategic management, shifting from being a process for firefighting to one of fire prevention. The recent

focus on social license has further led to the development of approaches to issue management that emphasize the need to work with social actors towards the common good.

Issue Management: Market Approach

Scott T. Davis

College of Business, Rikkyo University, Tokyo, Japan

Definition

A market-based approach to issues management is a method of identifying and managing issues that considers the public interest in addition to the strategic interests of companies. The goal of issue management within a market-based approach is to co-manage organizational and community resources to advance both private and public interests. This approach recognizes that non-market issues of broader societal concern are of strategic importance and emphasizes engagement in public policy debates to promote the development of public policies that would advance business interests. This market-based approach to issue management promotes a process of ongoing communication between companies and their stakeholders to achieve and maintain congruence, which leads to legitimacy. Legitimacy is gained by fostering stakeholder respect and understanding as an emergent process. Stakeholder salience is a critical factor in issue management within this approach, where issues are defined not only by the strategic salience of the firm, but also by the meaning attached to them by human agents. The emotional appeal and shared identity of issues can motivate stakeholders to work together toward a common goal. Although this approach recognizes the importance of actors outside the firm, stakeholders are primarily defined as external to the firm and their issues as externalities. This approach is characterized by several key concepts, including social issues, issue life cycles, legitimacy, and stakeholder salience.

Introduction

A market-based approach to issue management is characterized by a number of themes including:

1. Concern with the public interest in recognition of the shift in primacy of interests of the firm to the public
2. Social nature of issues or the “social dimension” of business
3. Dynamics of issues as issue lifecycles
4. Legitimation of the rights and freedoms of firms to conduct business

Wartick has observed that definitions of “issues” differ between the literature on business strategy, public policy, and the business and society (Wartick and Mahon 1994, p. 299). This difference is increasingly apparent when the focus of study is directed to the interactions between firms and social actors.

According to Heath, market approaches to issue management highlight the balance within the business community between the legitimate goals and rights of (1) society and (2) the free enterprise system (Robert L. Heath, p. 10). For Heath, this indicates a change in the objective of issues management from one concerned primarily with protecting the interests of the firm to one also considering interests mutual with society.

At the foundation of this approach is the recognition that non-market issues, which are of wider social concern, are of strategic importance. Heath highlights the importance for maintaining the operations of the firm by understanding the “knowledge and preferences of stakeholders” (Heath 2002, p. 211). Heath defines the goal of issue management within a market-based approach as being concerned with the engagement in public policy debates in order to promote the development of public policies that would in turn promote business interests (Heath 2002, p. 210). Accordingly Heath defines strategic issues management as the “co-management of organizational and community resources (both material and symbolic)” to promote both private and public interests (Robert L. Heath, p. 1).

This approach is defined by several key concepts, and among these social issues, issue life cycles, legitimacy, and stakeholder salience are of particular significance and will be discussed here.

Social Issues

As opposed to the firm centric approach to strategic issue management and its concern with the power to control, a market-based approach to issue management takes the market as its center and considers the ability of firms to influence and be influenced socially. Here issue salience is no longer based primarily on the interests, responses, and resources of the firm, but also by their “degree of social salience” (Clark et al. 2017, p. 1137). In terms of a theory of issue management, this means that there is a shift in the definition of issues as comprising “opportunities or threats” for the firm, to a deeper consideration of issues as being either consistent or contested in terms of their meaning for society (Clark et al. 2017, p. 1141).

Market-based approaches to issue management center on the concept of a social issue and the key question becomes therefore what constitutes a social issue and how can a social issue to be identified by a firm? In their seminal review of the corporate issue construct literature, Wartick and Mahon identified the three themes of: (1) impact, (2) controversy, and (3) expectational gaps, each with their own specific characteristics and weaknesses (Wartick and Mahon 1994, pp. 295–299).

The issue as impact construct is largely based on the work of Ansoff (as discussed in the previous section) and refers to external environmental issues that impinge on the firm. The weakness here is that social issues that are not seen to impact the firm are not recognized as corporate issues – without recognized firm impact; therefore, there is no social issue. Controversy, as the name suggests, identifies issues as the subject of a controversy – a dispute between actors with different interpretations of a particular situation or trend. This conceptualization also has limits as a guide for practice according to Wartick and Mahon in that it is difficult to predict. Expectation gaps have

been defined differently over time. Definitions of issues as gaps in expectations can be traced back to Jacoby who defines a social problem as a “gap between society’s expectations of social conditions and the present social realities” (Jacoby 1971, pp. 35–36). Post later defined social issues as gaps between firm performance and the public’s expectations of performance (Post 1978, p. 283).

Despite the apparent distinction between these three themes, Wartick and Mahon question the utility of this classification. Wartick and Mahon maintain that for a social issue to exist, there needs to be both controversy and a gap in expectation (Wartick and Mahon 1994, p. 300). Furthermore, they suggest that rather than focusing on the impact of issues themselves, the focus should be directed to the “impact of the possible resolution to the issue that is intended to close the gap” (Wartick and Mahon 1994, p. 302).

Based upon this, Wartick and Mahon proposed a reformulation of the issue construct where an issue is defined as:

“(a) a controversial inconsistency based on one or more expectational gaps (b) involving management perceptions of changing legitimacy and other stakeholder perceptions of change in cost/benefit positions (c) that occur within or between views of what is and/or what ought to be corporate performance or stakeholder perceptions of corporate performance and (d) imply an actual or anticipated resolution that creates significant, identifiable present or future impact on the organization.” (Wartick and Mahon 1994, p. 306)

Taking society as the starting point, Ryberg subsequently defined a social issue as a: “gap between social perceptions of business behavior or performance and social expectations about what that performance should be” (Ryberg 1982, p. 231). Galbreath later posed a broader definition of a social issue as comprising “anything that is found wrong with society” (Galbreath 2009, p. 112). Based upon the work of Ogburn and Duncan (1964) and Merton (1968), Galbreath identifies four aspects as constitutive of a social issue: (1) collective, not just individual awareness of wrong, (2) regional and temporal relativity as opposed to universality, (3) assumed existence of a solution or better way, and (4) desirability of its

resolution (see also: Galbreath 2010; Galbreath and Benjamin 2010).

Stressing the importance of solution and resolution, Lamertz has defined a social issue as:

“socially constructed disruptions of an institutional order that structures purposeful exchanges between actors. Under these conditions, issue evolution resembles an ongoing sense-giving battle in which actors seek to restore the order by imposing their unique solution preferences on the situation.” (Lamertz et al. 2003, p. 82)

Arguably this represents the breakdown of hierarchy-based issue management frameworks and the subsequent resort by the parties involved to the market in search of resolution. For Lamertz, issues can be:

“conceptualized as contests over the creation of meaning, arising as social actors disagree over the causes and consequences of events that precipitate structural failure of the negotiated order. In a symbolic interactionist framework, issues are therefore not seen as objective descriptions of events, but as reflections of a dynamic interaction between the participants in an enacted structure, who engage in a power struggle over the meaning constructed for the underlying objective conditions.” (Lamertz et al. 2003, p. 86)

Not all theorists assume that social issues are limited exclusively to contested issues or gaps in expectation. Clark, Bryant, and Griffin have also identified social consensus as a possible basis of issues and argue that the judgment of an issue as either contested or consensual will influence how the firm perceives the issue and the extent to which it will engage with it (Clark et al. 2017, p. 1138).

Social Issue Life Cycles

The dynamics of issue life cycles is a key theme within the market-based approach (Bonardi and Keim 2005; Clark et al. 2017, p. 1140). In contrast to the concern within the strategic approach with unmanaged issues that spin out of control to become crises, in the market-based approach, focus is given to the changes in the definition and significance attributed to issues over time as issue lifecycles. Social issues are widely seen as

cyclical in nature – as shaped by an inherent tendency to slowly emerge, wax, and then wane as interest in them diminishes or as a result of their resolution. Clark has observed that much of the literature on issues management is concerned with the “dynamic, transitory, or cumulative effect of issues over their life cycle” (Clark et al. 2017, p. 1140). Within this approach, the cumulative effects over time of single as opposed to multiple issues are given particular attention (Clark et al. 2017, p. 1140).

Stressing the social context (the inherently societal nature) of social issues, however, Lamertz, Martens, and Heugens have disputed the life-cycle model of social issues and sought to substitute it instead with a symbolic interactionist framework which: “avoids attributing independent ontological status to issues or events. Instead, the framework assumes that key social actors construct a social issue through interpretations of key events” (Lamertz et al. 2003, p. 84). For Lamertz, Martens, and Heugens, therefore, issues evolve not in cycles of public attention, but instead in the context of ongoing negotiation of meaning through relationships.

Working from Weick’s theory of sensemaking SEE {Weick, 1979 ¥6059;Daft, 1984, r00506;Daft, 1984, r00506;Weick, 1993, r01359;Weick, 1995, r00848;Weick, 2001, r01892}, Lamertz, Martens, and Heugens depict the process of issue evolution as being: “less a natural process of fluctuating public attention and more a social process of constructing and negotiating meaning in a context of ongoing social relations and transactions” (Lamertz et al. 2003, p. 84), thus recognizing the socially constructed nature of issues as relativities within the wider societal context. Seen sequentially then, the development of an issue therefore starts with an enacted structure, which receives public attention after failing due to the application of pressure, thus leading to the definition of an issue, an ensuing institutional redesign and lastly in a reenactment, which signals issue resolution (Lamertz et al. 2003, p. 84).

Issue Management as Competitive Advantage

Heath has argued that the ability to manage social issues constitutes an organizational capability from which firms may derive a competitive advantage.

Heath identifies four such abilities by which the firm enhances its ability to manage social issues by:

- Planning and managing strategic business processes – “thinking and acting smart”
- Knowing and achieving appropriate standards of corporate responsibility – “getting the house in order”
- Monitoring issues – “scouting the terrain”
- Engaging in strategic public policy dialogue – “engaging in tough defense and smart offence” (Heath 2002, p. 211)

While recognizing the performance benefits of social issue engagement for firms, however, Hillman and Keim argue that these capabilities are an easily copied level of a competitive advantage.

Hillman and Keim have observed that:

“investing in stakeholder management may be complementary to shareholder value creation and may indeed provide a basis for competitive advantage as important resources and capabilities may be created that differentiate a firm from competitors. On the other hand, participating in social issues may be seen at best as a transactional investment easily copied by competitors.” (Hillman and Keim 2001, p. 135)

In order to create a competitive advantage that results in economic value creation, firms must therefore engage in social issue involvement that goes beyond transactional actions. Hillman and Keim argue that social performance must be separated into two forms – (1) stakeholder management and (2) social issue participation – in order to measure the economic value created by social issue engagement (Hillman and Keim 2001, p. 126).

Legitimacy

The interpretation of issue management as an ongoing process of securing legitimation by identifying and addressing issues indicative of gaps between social perceptions and expectations of firm performance and behavior is another important theme in the market-based approach to issue management.

Heath, working from the discipline of public relations, has identified legitimacy gained through the promotion of respect and understanding from stakeholders as another benefit for firms for engaging in social issue management. For Heath “ultimately the objective – and advantage – of issues management is to make a smart, proactive and even more respected organization. This sort of organization is one that understands and responds to its stakeholders and stakeholders” (Heath 2002, p. 211).

In earlier work, Sethi refers to this state of understanding as congruence. For Sethi, this congruence between a firm’s goals with those of society forms the basis of legitimacy: “Corporations, like all other social institutions, are an integral part of a society and must depend on it for their existence, continuity, and growth. They therefore constantly strive to pattern their activities so that they are in congruence with the goals of the overall social system” (Sethi 1979, p. 64). A lack of congruence here results in a loss of legitimacy, which must be reduced in order for the firm to “maintain maximum discretionary control over its internal decision-making and external dealings” (Sethi 1979, p. 65).

Heath argues that legitimacy is not static, but the changing result of an ongoing and emergent process of communication between firms and their stakeholders and stakeholders in order to achieve and maintain congruence. For Heath, this means that “legitimate organizations cocreate and constitute themselves through communication” and that “harmony is cocreated as collective self-interests gain and reflect shared definitions of public interest” (Robert L. Heath, p. 1).

The inability to manage issues can result in a legitimacy gap developing between the social perception of either the performance or behavior of a firm in contrast with its expectations (Ackerman 1973). The opposite state of a legitimacy gap has been explored using the concept of a license to operate [*see entry on license to operate*].

Stakeholder Salience

In contrast to the strategic approach to issue management, wherein issues are defined by the firm in accordance with their strategic salience, the market approach also considers the role of stakeholders in the identification of issues.

This process is explained by Crable and Vibbert when they state that:

“Issues are not simply questions that exist. An issue is created when one or more human agents attaches significance to a situation or perceived ‘problem.’ These interested agents create or recreate arguments which they feel will be acceptable resolutions to questions about the status quo. Literally, then, people and groups of people ‘make’ issues out of matters in which they have an interest.” (Crable and Vibbert 1985, p. 5)

Within the market approach, understanding the significance of issues to stakeholders plays an important role in issue management. According to Bundy et al. (2013, p. 354), there are several factors beyond immediate material interests that can explain why stakeholders may identify and prioritize certain issues. One such factor is the emotional appeal of issues to stakeholders. Issues may evoke strong emotions in stakeholders and create an emotional connection that extends beyond the expected impact of the issue. This emotional connection can make the issue more important to the stakeholders than it would have been based on a purely rational consideration of its immediate impact (Bansal and Roth 2000, p. 729). In other instances, stakeholders may also pursue issues that relate to and reinforce their shared identity. This can help to promote solidarity among group members and strengthen the bond between them, even if the issue itself

may not directly align with their rational interests as a group. By pursuing issues that are meaningful to their collective identity, stakeholders may be motivated to work together towards a common goal (Rowley and Moldoveanu 2003, p. 211).

Summary

Market-based approaches to issue management go beyond the firm centricity characterizing strategic approaches (see entry on ► “Issue Management: The Strategic Approach”) by acknowledging the importance of issues identified by social actors and recognizing that stakeholders may both identify their own issues and attribute their own meaning to issues (Van Offenbeek and Vos 2016, pp. 54–55). While this approach may therefore acknowledge the role and importance of actors outside the firm, stakeholders continue to be defined as external to the firm and their issues as externalities from the firm’s perspective. Although this approach explores the social context within which firms and their activities are embedded, it does not go beyond the essential dichotomy dividing firms and stakeholders characteristic of the strategic approach.

Issue Management: The Network Approach

Scott T. Davis
Rikkyo University, Tokyo, Japan

Definition

The network approach to issue management is a framework that seeks to address the limitations of both the strategic and market approaches to issue management by recognizing that firms are only one participant among others in a broader network of stakeholders. The network approach to issue management has three main themes: a non-firm-centric definition of stakeholders and issues, the business environment as a multistakeholder network, and issue resolution in a network as a process of system (relationship) change. This approach defines issues as being the characteristics of networks of relationships as systems and seeks to manage them through mechanisms such as issue-focused stakeholder management, detached networks, issue evaluation, and the integrative framework of issue and stakeholder management. Overall, the network approach to issue management recognizes the importance of managing stakeholder relationships and promoting the legitimacy of the issue management process and its outcomes by incorporating stakeholder perspectives into the identification of issues and the formulation of plans for their resolution. The network approach to issue management therefore aims to realize an operational framework that enables stakeholders and issues to be managed through integrative efforts.

Introduction

Three themes characterize the network approach to issues management:

1. A non-firm-centric (not predicated on a firm's agenda) definition of stakeholders and issues

2. The business environment as a multi-stakeholder network. Integration of issue identification and stakeholder management
3. Issue resolution in a network as a process of changing systems (relationships)

This approach is defined by several key concepts, of which issue focused stakeholder management, detached networks, issue evaluation, the integrative framework of issue, and stakeholder management will be discussed here.

Addressing the Limits of the Market Approach to Issue Management

The network approach to issues management attempts to resolve shortcomings seen as limiting the utility of the market approach, which implicitly attributes centrality to firms. Roloff maintains that stakeholder theory as formulated by Freeman tends to locate the firm at the center of stakeholder networks (Roloff 2007, p. 234). Roloff argues that unlike Freeman's formulation of stakeholder theory, a network approach to issue management does not presume the centrality of the firm or its interests. Instead, a key characteristic of this approach is to understand that firms are just one participant among others comprising a wider network (Roloff 2007, p. 234). Following Mason and Mitroff (1981), Mahon, Heugens, and McGowan contend that issues can be "wicked problems" – too complex to be understood by any one actor alone or solved "in a piecemeal fashion" from a singular perspective (Mahon et al. 2018, p. 5).

The theory and practice of issues management changes when firms are seen to be one individual component among others comprising multi-stakeholder networks. Harrison and St. John (1996) describe these networks as "webs of interdependencies created among stakeholders in order to deal with increasingly uncertain and competitive environments" (Harrison, and St. John 1996, p. 48), the management of which can constitute a competitive advantage for firms.

According to Mahon, Heugens and McGowan issues are objectified as externalities within

market-based approaches to issue management as a result of an artificial division maintained between issues and stakeholders. For Mahon, Heugens, and McGowan:

“two separate frameworks have existed for the analysis of social predicaments in which businesses play a role: issues management and stakeholder management. . . we argue that the chasm dividing these two literatures is artificial, and potentially obstructive to the advancement of our knowledge of the position of business in contemporary societies.” (Mahon et al. 2018, p. 1)

A network-based approach seeks not to dismiss issues by objectifying them as externalities but instead define them as the characteristics of networks of relationships as systems.

The recognition and understanding of the non-centricity of firms in networks and the role of stakeholders, and of managing relationships with stakeholders, has been the starting point for the development of several frameworks taking a network-based approach. Within this literature, two themes are of particular interest: (1) how issues develop within networks and (2) how issue management and stakeholder management can be reintegrated within a network-based approach.

Issue Development Within Networks

Roloff has analyzed the dynamics of issue development within networks and has defined two forms of stakeholder management within networks: organizational and issue. In the organizational type, the firm itself features as the focus point while in the issue type the relationships with external social groups serves as the focus (Roloff 2007, p. 233). In comparison to stakeholder management that is centered on the organization, issue-focused stakeholder management aims to promote the legitimacy of the process and its results by incorporating the perspectives of stakeholders into the identification of issues and the formulation of plans for their resolution. See Roloff (2007, p. 233). Roloff defines the issue management process within stakeholder networks as comprising a life cycle of seven stages: “initiation, acquaintance, first agreement, second

agreement, implementation, consolidation and institutionalization or extinction” (Roloff 2007, p. 238).

Roloff’s seven stages are:

1. **Initiation:** Several entities identify an issue of common concern, which would not be best managed by independent action (Roloff 2007, p. 238).
2. **Acquaintance:** Network members share relative perspectives on issue and particular (often incompatible) opinions. Storytelling is a frequently used method to attain mutual understanding (Roloff 2007, p. 239).
3. **First agreement:** Based upon shared issue-related knowledge of networks, members construct descriptions of issue situations and a problem definition (Roloff 2007, p. 240). See Rauschmayer and Wittmer (2006).
4. **Second agreement:** Identify options for resolution, select optimal solution strategy (Roloff 2007, p. 241).
5. **Implementation:** “Shifts from communication to cooperation and action” (Roloff 2007, p. 241) and is often marked by the withdrawal of unsatisfied members.
6. **Consolidation:** Period characterized by the formalization of hitherto informal rules (Roloff 2007, p. 242).
7. **Institutionalization or extinction:** Some stakeholder networks become formalized as institutions or disband at the conclusion (or failure) of their action and subsequent transfer of responsibility to a government or other established actor.

Roloff hereby defines the development of issues as the development of the interaction between stakeholders as they seek to resolve issues best managed collectively.

Detached Networks as a Crisis Phase of Issue Management

Boutilier has argued that networks are an important factor for issue management because of their role as a form of governance. Boutilier maintains that:

“When both markets and hierarchies do not provide governance, the default provider is the network” (Boutilier 2011). By default, therefore, firms are not in control of issues when a network model of governance has been sought. Accordingly, Boutilier has identified another potential phase in the management of issues when seen from a network approach – a crisis phase wherein networks separated from firms have congealed around issues.

For Boutilier: “Where the rule of law is thin and governance defaults to whatever can be agreed upon by a network of stakeholders, the campaigning continues indefinitely until the alliances stabilize around a consensus that can be turned into a network norm. This is not an automatic or guaranteed outcome. Only particular kinds of network structures will permit this to happen. Shaping the stakeholder network into one of these structures requires knowledge of the social capital among all the stakeholders.” Boutilier Loc 895 (Boutilier 2011, p. 41).

Boutilier’s contention is thus that networks can be described in terms of connections (exchanges) of social capital and identifies social capital as the key to understanding stakeholder collaboration (Boutilier 2011). For Boutilier, understanding the meaning and function of social capital in networks is of importance because it is the basis of normative relationships within networks and therefore also the material by which they are shaped and can also be reshaped. According to Boutilier, “social capital in stakeholder networks tells us where the power, influence, and collaborative capacity are located” (Boutilier 2011, p. 59).

According to Boutilier, an issue can become a crisis for a firm when various networks emerge around different interpretations of the issue, which conflict with the firm’s preferred or assumed frame. When issues are perceived as a crisis by firms, it is often due to the existence of these separate networks, which Boutilier refers to as “detached networks.” A detached network has its own unique perspective (“frame”) on the issue, its own justifications for its members’ actions, and its own set of norms and values (“normative code”) that guide membership within the socio-political alliance.

According to Boutilier:

“the stakeholder network approach aims to prevent the formation of detached networks in the first place. Where they have already occurred, it aims to meld the networks. This entails creating a unified frame for the issue and a unified code of member behavior. Such a code creates the groundwork for network governance and therefore makes it possible to re-legitimize an organization’s resource access.”

When firms consider their ability to participate in webs of interdependencies as a potential strategic skill, the relevance of being able to quantify collaborative capacity in partnerships becomes evident.

Reintegrating Issue and Stakeholder Management: Mahon, Heugens, and McGowan “Issue Evaluation”

Mahon, Heugens, and McGowan identify a weakness in issue management wherein issue management is separated from the management of stakeholders.

For Mahon, Heugens, and McGowan:

“all social predicaments have an issues side as well as a stakeholder side and that a dual focus on both issues and stakeholders is therefore essential to understanding the evolution of these predicaments and crucial to managerial dealings with these issues. . . . If we want to understand social predicaments in their entirety, we need a framework that can accommodate issues and stakeholder considerations simultaneously. Or to put it in another way, we need to deal with the what (issue) and the who (stakeholders) simultaneously and continuously as the issue unfolds (with competing issue definitions) and as stakeholders enter and exit the situation over time. This is the problem facing managers in dealing with such situations—the issue (the substantive content) and the players involved (stakeholders) need to be addressed simultaneously.” (Mahon et al. 2018, pp. 1–2)

Mahon, Heugens, and McGowan aim to address the disconnection between issue management and shareholder management by developing a combined model that they term “issue evaluation” (Mahon et al. 2004, p. 175). Mahon, Heugens, and McGowan have formulated this model using network theory in an effort to reconcile the apparent separation between issue and shareholder management. The model is based on the premise

that the identification of issues is a cognitive process and incorporates an understanding of the organization of collective action within networks (Mahon et al. 2004, pp. 177–178). At the core of this model is Weick's theory of sensemaking whereby actors ascribe meaning to issues. According to Weick, actors attribute meaning to complex issues by an ongoing process of choosing from among multiple possible interpretations (Weick 1979). Actors are therefore constantly ascribing meaning to issues.

The assignment of varying interpretations, which then results in distinct actions and outcomes, is of great significance in this context (Thomas et al. 1994). The sensemaking process results in issues being comprehended and labeled on two levels: substantive and analytical. The substantive labeling precedes the analytical labeling, as it involves the attribution of meaning while analytical labeling categorizes the issue as either an opportunity or a threat (Mahon et al. 2004, p. 179). According to Mahon, Heugens, and McGowan, the process of attributing meaning within networks to issues is not arbitrary, but rather shaped by (1) the structural characteristics of the network and (2) the position of individual actors within the structure (Mahon et al. 2004, p. 177).

Network density and centrality have also been identified as key concepts for understanding network structure and firm position (Rowley 1997, pp. 876–900). Density is a defining characteristic of a network's structure, comprises of the number of ties linking actors in a network, and is characteristic of the network as a whole (Mahon et al. 2004, p. 178). The number of stakeholders involved in the network and the extent of relationships between them gives density to the network. Networks display different degrees of density. Centrality is an active position relative to all other actors in a network. Increasing centrality enables a greater ability to assert influence over other members (Mahon et al. 2004, p. 178). Network density influences issue management by shaping the classification of issues. The denser the network, the greater is the sharing of "substantive labeling" by means of intensive cross communication (Mahon et al. 2004, p. 179). Higher levels of network density result in lower variation

in substantive labels to categorize issues among actors in the network (Mahon et al. 2004, p. 179). Centrality also influences issue management. A firm's relative centrality within a network influences its ability to define and manage issues. Relative network centrality increases with access to the greatest number of other network members (Neville et al. 2011, pp. 359–361).

Network density and centrality also influence the collective responses of actors within a network. Actors sharing subjective labels, and therefore similar strategic positions on issues, tend to form coalitions to resolve issues. The formation of coalitions marks the transitional stage between the evaluation of individual issues by individuals and the collective resolution of these issues (Mahon et al. 2004, p. 181). Coalitions that are established to resolve issues are more likely to occur between actors that possess similar substantive characteristics (Mahon et al. 2004, p. 181). As the degree of network interconnectedness decreases, the quantity of fully competing coalitions for issue resolution increases. Increasing centrality within the network increases the likelihood of simultaneous membership in multiple issue resolution coalitions. An increase in the density of a network also has the effect of exposing firms to the attention of a larger number of stakeholders. Conversely, relative centrality within dense networks also enhances the capacity of firms to resist stakeholder demands (Rowley 1997, p. 887). Coalition membership is not exclusive – actors may simultaneously belong to multiple coalitions. Actors with multiple inclusion can act as gatekeepers and brokers within the network (Mahon et al. 2004, p. 182).

Based upon this framework, Mahon et al. have proposed that firms should monitor the network density where they operate and the substantive and analytical labels used for issues by other network members, especially those used by members with strong positions, and engage in issue management in consideration of their relative structural position in networks and seek a position of network centrality. Where centrality is low, especially in issues of importance, firms should seek to influence the most central actors (Mahon et al. 2004, p. 184).

Offenbeek and Vos's "Integrative Framework"

Subsequent to Mahon et al., Offenbeek and Vos have proposed an integrative framework for managing stakeholders and issues by reintegrating the separate, parallel streams of theory that have developed concerning stakeholder and issue management (Van Offenbeek and Vos 2016, p. 44). Underlying their framework is Weaver's classification of problems in communication (Weaver 1949) and Carlile's work on knowledge transfer over boundaries (Carlile 2004).

Weaver defines three levels of problems in the process of communication, which he defines as the "procedures by which one mind may affect another" (Weaver 1949, p. 3). These three levels are (1) technical – the degree of accuracy by which information is relayed, (2) semantic – the precision with which meaning is conveyed, and (3) effectiveness – the extent to which the meaning conveyed elicits recipient behavior as desired by the sender (Weaver 1949, pp. 3–4). These three problems can be expressed as attaining "accuracy of transference" on the first level, approximation of intended to interpreted meaning on the second, and the success of promoting desired behavior on the third (Weaver 1949, p. 5).

Carlile defines three levels of complexity that represent qualitatively distinct boundaries across which knowledge must be transmitted (Carlile 2004). Adopting Weaver's three problems as three levels of communicative complexity – syntactic, semantic, and pragmatic – Carlile explores the process by which knowledge is managed across boundaries of increasing complexity as defined by three properties of knowledge: difference, dependence, and novelty (Carlile 2004, pp. 555–556). Difference is the degree of variety among domain-specific knowledge between different actors. Knowledge is domain specific and therefore different between actors and requiring effort in order to assess and share (Carlile 2004, p. 556). Dependence is the condition wherein actors must consider the goals of others in order to attain their own goals. Carlile maintains that in the absence of dependence "difference is of no consequence" (Carlile 2004, p. 556) and that

difference gains complexity with increasing dependence in terms of both activities and resources. The creation of common knowledge becomes important here due to it being a necessary condition to manage dependence. Novelty is the degree of unfamiliarity with the knowledge common to a domain, and the lack of common knowledge required to assess and share this knowledge. For Carlile "when novelty is present both the *capacity* of the common knowledge to represent the differences and dependencies now of consequence and the *ability* of the actors involved to use it become important issues [*italics original*]" (Carlile 2004, p. 557).

Using these three knowledge boundaries, Carlile then explores the process whereby knowledge can be effectively communicated across domains by means of the three processes drawn from Weaver: transfer, translation, and transformation (Carlile 2004, p. 558). The transfer of knowledge is required to cross the "information processing boundary." Increasing novelty increases the difficulty of transferring knowledge due to the insufficiency of existing lexicons to represent the newly emergent differences and dependencies. Translating knowledge is therefore required to cross this "interpretive boundary." Increasing novelty makes the meaning of differences and dependency unclear or ambiguous. Therefore, requiring firms to (1) address interpretive differences across boundaries and (2) understanding different interests of actors and making trade-offs. Trade-offs for Carlile constitute "a political process of negotiating and defining common interests" (Carlile 2004, p. 559).

Transforming knowledge is seen as essential for overcoming "pragmatic/political boundaries," which are created by differences in interests between actors. These differences can make their dependencies problematic and lead to conflicts that require resolution. When these conflicts arise, they create pragmatic boundaries that need to be addressed. The resolution of these boundaries often incurs costs for the actors involved. This cost is dependent on the knowledge that has been invested in the particular practice, making it a significant stake for all stakeholders involved. Therefore, it is important to understand that

transforming knowledge can help to mitigate these pragmatic boundaries, reduce the costs incurred, and ensure that the interests of all stakeholders are aligned. By doing so, it can create a more effective and efficient system for all parties involved.

For Carlile, conflicts in interests can result in negative consequences in the form of costs, including those incurred in learning new knowledge and transferring existing knowledge (Carlile 2004, p. 559). Carlile states that the costs of crossing a pragmatic boundary are incurred in the development of three abilities: representing current and novel forms of knowledge, learning and understanding the consequences of change involved, and transforming one's own domain-specific knowledge to achieve change (Carlile 2004, p. 559).

Offenbeek and Vos aim to bring together stakeholder and issue management by using Carlile's knowledge integrative framework. They aim to develop a "multilayered stakeholder-issue framework" that enables the analysis of stakeholders and their issues as they change over time (Van Offenbeek and Vos 2016). To do this, they propose two bridges to link the management of stakeholders and issues, one linking stakeholders to issues and another linking issues back to stakeholders. Through this integration of stakeholder and issue management, they hope to enhance the understanding of the interplay between stakeholders and their issues and the impact that they have on each other over time (Van Offenbeek and Vos 2016, p. 45).

The stakeholders to issues bridge are based on an examination of the weaknesses of "hard complexity." A hard complexity approach to identifying stakeholders concentrates on actors supporting issues which relate to the interests of a firm and its goals. The result is a set of stakeholders defined upon criteria of fixed interests and power relations, which emphasizes influenced over influential stakeholders, ignores emerging issues by virtue of being based upon a fixed set of actors, and emphasizes stakeholders over their issues. Offenbeek and Vos instead contend that it is the significance of issues for stakeholders that should be emphasized (Van Offenbeek and Vos

2016, p. 45). The second bridge from issues to stakeholders emphasizes the nature of issues as an enactment of stakeholder interests without which issues would not exist. Within this Offenbeek and Vos's central contention is that issues are a form of knowledge because they are enacted by stakeholders within both a subjective and temporal context and are therefore bounded by a perception (awareness and interpretation), which may not be shared by other stakeholders (Van Offenbeek and Vos 2016, p. 46).

Drawing on the frameworks of both Weaver and Carlile, Offenbeek and Vos define three forms of boundaries characterizing issues as knowledge: *processing* where knowledge is treated as a thing to be stored and retrieved, *interpretation* where common meaning is required to share knowledge among others, and *political* where common interest is required to share knowledge among actors with differing interests. These three processing, interpretative, and political levels are accumulative and represent additional relational properties for issue management. Based upon this, they define three perspectives for examining "stakeholder-issue connections" – syntactic, semantic and pragmatic – to guide issue management by firms (Van Offenbeek and Vos 2016, p. 47).

Implementation of this issue management framework requires firms to approach stakeholders and issues from three perspectives: the commonality of issue identification between stakeholders, the meanings attributed to issues by stakeholders and the dependencies between them, and the nature of the tradeoffs involved in possible actions to address the issues of different stakeholders. The commonality of an issue is expressed by the number of stakeholders voicing an issue over time. Dependency among issues is expressed on three levels: pooled, sequential, and reciprocal (Van Offenbeek and Vos 2016, p. 47). Pooled dependency refers to issues that require the same resources be used in their resolution. Inadequate resources require issues be prioritized for allocation. Sequential dependency refers to a situation wherein the resolution of one issue is dependent upon the resolution of another. "Chains of issues" determine paths of action whereby the history of previous choices of issues for solution

shapes the scope of issues that can be selected to be addressed subsequently. Reciprocal dependencies are where issues are intercoupled in such a way as to incur tradeoffs when managing them. Stakeholders will act to promote tradeoffs favorable to their own interests. Here Offenbeek and Vos suggest that firms weigh the relative merit of possible tradeoffs based on the legitimacy of stakeholders and their future potential to influence. At the core of this integrative framework is the concept of “issue weight,” a measure calculated as the degree of issue commonality among stakeholders compared against the average legitimacy (perception of ability to be influenced or to influence) of stakeholders (Van Offenbeek and Vos 2016, p. 47).

Summary

The network approach to issue management seeks to address the complexity of issues is due to their subjective relativity and temporal dynamism thus avoiding the perceived limitations of approaches, which assume the centrality of the firm’s interests (see entry ► “[Issue Management: The Strategic Approach](#)”) and the disconnection between the management of stakeholders from that of issues inherent in market approached to issue management (see entry on ► “[Issue Management: Market Approach](#)”).

Issue Management: The Strategic Approach

Scott T. Davis
Rikkyo University, Tokyo, Japan

Definition

The strategic approach to issue management is informed by a hierarchical mode of governance that gives centrality to the firm and priority to the attainment of corporate goals. The strategic

approach to issue management is a managerial function focused on identifying and planning for the impact of external negative influences on a firm's strategy and its implementation. This strategic approach to issue management is an organizationally mediated and subjective process of identifying and interpreting issues that is informed by strategic cognition. It aims at promoting and protecting a firm's interests by identifying issues, evaluating their strategic implications, and analyzing the motivations and strengths of external entities promoting them as issues. This approach involves three major activities: issue identification, corporate proaction, and inclusion of public affairs issues in established decision-making processes and managerial functions. The implementation of strategic issue management involves procedures for scanning and situational analysis of the business environment. Key concepts of this approach include Strategic Issue, Publics, Trends, Strategic Cognition, and Issue Salience.

Introduction

The strategic approach to issue management is based on hierarchical modes of governance that are essentially corporate-centric; in that it gives centrality to the firm and priority to the attainment of corporate goals. Here, firms develop procedures for the rational and efficient management of activities and resource utilization in order to implement strategies and overcome problems. Issues seen as originating from the external environment beyond the corporation are evaluated as either opportunities or as potential obstructions to the pursuit of a firm's strategic interests, with the tendency being to emphasize issues as potential problems. Issue management here thus aims at promoting and protecting a firm's interests and is centered around the identification of issues, the evaluation of their strategic implications, and the analysis of the motivations and strengths of the external entities promoting them as issues.

This definition of issue management as a managerial function to identify and plan for the impact of external, usually negative, influences on a

firm's strategy and its implementation has a long history and remains of relevance to business today. Fleming has defined issue management as a managerial function. According to Fleming, the management of issues "consists of three major activities: issue identification, corporate proaction, and the inclusion of public affairs issues in established decision-making processes and managerial functions" (Fleming, 1980, p. 35). The implementation of strategic issue management was typified by procedures for the scanning and situational analysis of the business environment. This approach is defined by several key concepts, and among these, Strategic Issue, Publics, Trends, Strategic Cognition, and Issue Salience are of particular significance and will be discussed here.

Strategic Issues

Igor Ansoff was among the earliest and most significant contributors to the field of Strategic Issue Management, which emerged from the study of strategic planning. Although the concept of a strategic issue was also used in strategic planning, within Strategic Issue Management "strategic" was taken to mean important or significant. Strategic issue management was characterized by environmental scanning aimed to identify opportunities and advantages in the form of threats and opportunities without, and strengths and weaknesses within, using methods still in widespread use today such as SWOT analysis.

Ansoff provides an early definition of issues management which differentiates it from the function of strategic planning by defining a distinction between strategic planning and strategic issue analysis (Ansoff, 1975, p. 31).

For Ansoff, strategic planning is a periodically implemented process concerned with strategy and is organizationally focused, wherein "strategic information needs derived from decisions," in contrast to strategic issue analysis, which is defined as an ongoing process concerned with discontinuities and surprises from all sources and wherein "feasible decisions are determined by available information" (Ansoff, 1975, p. 31).

Ansoff defines Strategic planning as a system for “converting environmental information about strategic discontinuities into concrete action plans, programs, and budgets” (Ansoff, 1975, p. 22). To be effective, this requires that information must be timely and sufficient. Timely as in available at a time that enables its use in planning and sufficient to evaluate a trend’s impact on the firm and therefore to plan responses (Ansoff, 1975, p. 22). Ansoff’s critique of the weaknesses of strategic planning as a form of issue management is of its reliance on this timeliness and sufficiency of information – the weakness here for Ansoff is in the limitations of this to make use of “weak signals” that potentially give foresight to firms.

Ansoff seeks to address the question of how organizations should deal with emerging issues that present as “weak signals” in turbulent environments. Ansoff proposes (defines) a new concept of strategic issue management to facilitate better planning for managing subtle (incipient) changes in the business environment. Ansoff’s goal is to answer the question of how businesses should cope with growing challenges that appear as “weak signals” in chaotic times. He defines a new concept of strategic problem management to make it easier to plan for subtle changes in the business environment.

Ansoff proposes a definition of issue management for utilizing weak signals in turbulent environments based on four characteristics: flexible organization, real-time, strategic loops, and action-based.

1. “organizational flexibility” whereby “both the planning and implementation of strategic issues are determined not by the organizational structure but by the nature of the problem involved”
2. implemented in real time,
3. based upon a process defined by (a) operating (are budgets and plans being followed?) and (b) strategic (has the “the strategic issue has been well identified, whether it deserves the priority assigned to it, and whether the action strategy has been well chosen”) feedback loops. Issues resulting from vague trends are dealt with by the strategic loops.

4. “strategic issue management is an action, and not a purely planning, system” – “planning and implementation are not separated” (Ansoff, 1975, p. 31).

Ansoff later extended the concept of strategic issue management to include the resolution of, in addition to planning responses to, issues. For Ansoff, unless those separate roles are established, “strategic issue management may degenerate into paralysis by repeated analysis” (Ansoff, 1980, p. 134).

Taking a more nuanced approach Ansoff defines a strategic issue as a:

forthcoming development, either inside or outside of the organization, which is likely to have an important impact on the ability of the enterprise to meet its objectives. An issue may be a welcome issue, an opportunity to be grasped in the environment, or an internal strength which can be exploited to advantage. Or it can be an unwelcome external threat, or an internal weakness, which imperils continuing success, even the survival of the enterprise. Frequently, external threats, because they signal significant discontinuities in the environment, can be converted into opportunities by aggressive and entrepreneurial management. (Ansoff, 1980, p. 133)

Ansoff wrote extensively on the importance of issue identification and definition for effective decision-making and management (See: Ansoff, 1975, 1980, 1987). Ansoff has observed that an important part of issue management is to understand that not all issues are strategic and that in order to be relevant to a specific firm, an issue must pose an identifiable “potential future impact of the trends on the future performance of the enterprise” (Ansoff, 1980, p. 136). In short, a social issue becomes strategic for Ansoff to the extent that it impinges in some manner on a firm’s strategic intent and objectives.

Publics and Issue Management

A key concept in this approach to issue management is that of the “public,” and that firms face “publics” over issues. For Grunig and Repper, publics form around the common recognition of

a problem among stakeholders regarding firm plans or action: "Publics form when stakeholders recognize one or more of the consequences as a problem and organize to do something about it or them" (Grunig & Repper, 1992, p. 124). Issue management for Grunig is the anticipation of these issues and the development of a corresponding organizational response to them (Grunig & Repper, 1992, p. 124). Grunig and Repper also maintain that publics, unlike stakeholders, are reactive, not passive. For Grunig and Repper: "Many people in a category of stakeholders – such as employees or residents of a community – are passive. The stakeholders who are or become more aware and active can be described as publics" (Grunig & Repper, 1992, p. 125).

Grunig and Repper also maintain a distinction between publics and markets based upon the difference of choice. For Grunig and Repper the:

distinction between publics and markets is important for understanding the nature of publics and for clarifying the difference between public relations and marketing. Organizations can choose their markets, but publics arise on their own and choose the organization for attention. Publics, in contrast, organize around issues and seek out organizations that create those issues to gain information, seek redress of grievances, pressure the organizations, or ask governments to regulate them. As publics move from being latent to active, organizations have little choice other than to communicate with them. (Grunig & Repper, 1992, p. 128)

Grunig and Repper divide publics into four categories: "all-issue," "apathetic," "single issue," and "hot issue publics." As the terminology suggests, all issue publics are concerned and act on all issues; apathetic publics are the opposite and act on none. Between these two extremes are single issue publics which focus on specific issues which may or may not be widespread and hot issue publics which are actively engaged by issues that are widely accepted, widely covered in the media, and similarly motivate most of the community or population (Grunig & Repper, 1992, p. 139).

Crable and Vibbert have argued that issues become part of the public agenda because an agent has made a problem into an issue. For Crable and Vibbert:

issues are not simply questions that exist. An issue is created when one or more human agents attaches significance to a situation or perceived 'problem.' These interested agents create or recreate arguments which they feel will be acceptable resolutions to questions about the status quo. Literally, then, people and groups of people 'make' issues out of matters in which they have an interest. Moreover, issues – while derived from 'problems' – are not exactly problems. They are situations in which relief but not total solution is found. Said another way, issues may be 'resolved' – in the sense of a temporary 'answer' – but they are never 'solved' in the sense of a final answer. (Crable & Vibbert, 1985, p. 5)

This position that publics create issues out of their perceptions of a problem is shared by other key theorists in the communication and public relations discipline of the time, including Jones and Chase (1979), Chase (1984), and Hainsworth (1990).

Trends

An important part of the strategic approach to issue management is the early detection and interpretation of issues. If an issue is a problem that has been given significance by an actor, thus creating a public, then a mark of an effective issue management function would be the ability to detect developing issues early in this signification process. Developing issues are defined as trends. Chase defined issues as "an unsettled matter which is ready for decision. Trends, on the other hand, are detectable changes which precede issues" (Chase, 1984, p. 38). This ability of being able to identify and follow trends is a distinguishing feature of issue management frameworks and models within the strategic approach.

Representative among these models is a framework known as the Chase-Jones process model (Chase, 1984; Jones & Chase, 1979). Still considered to be influential today (Coombs & Holladay, 2013), this model consists of five stages commencing with: (1) issue identification wherein trends are examined, (2) issue analysis where issues are researched, (3) issue change strategy options where firms devise and choose either reactive (actively oppose change), adaptive

(attempt to satisfy the demands of external publics) or dynamic responses (“creates and directs policy rather than merely reacts to policy trends established by other forces”), (4) organization of an issue action program designed to achieve the firm’s action goals for the issue, and finally (5) a stage where results are evaluated and the process is repeated as a cyclical process if necessary (Jones & Chase, 1979, pp. 9–21). Jones and Chase’s model distinguishes clearly between external and firm interests and stresses the importance of maintaining control when describing their definition of a dynamic response as a strategy that “anticipates and attempts to shape the direction of public policy decisions by determining the theater of war, the weapons to be used, and the timing of the battle itself” (Jones & Chase, 1979, p. 17). As can be inferred from the confrontational language, this model assumes primacy of the interests of the firm.

Overall, this issue management model is essentially a systematization of the external part of strategic management aimed to maintain the firm’s control over the course of important events and avoid regulatory infringement on business freedoms and rights (Grunig & Repper, 1992, p. 146). This model has been criticized for being little more than a systematization of prevailing public relations management functions under a new name (Ehling & Hesse, 1983).

Strategic Cognition

As organizations, firms do not respond directly and objectively to developments in their environments as issues. The process of identifying and interpreting issues is instead organizationally mediated and therefore also subjective.

This process by which firms identify and interpret issues has been the subject of extensive research. Dutton, another early and influential contributor to the definition of issues in business, developed a model of strategic issue diagnosis (SID) which contrasts to that of Ansoff. Unlike Ansoff’s earlier, more pragmatic formulations, Dutton conceptualized strategic issue diagnosis as a process of sense making that went beyond

the immediate needs of “decision events” (Dutton & Duncan, 1987, p. 280) to the extent that it could take place independent of strategy in order to avoid “the boundedness of decision making” (Dutton et al., 1983, p. 321).

Specifically, Dutton rejected the assumption that issues were objectively strategic, arguing instead that: “an issue becomes strategic when top management believes that it has relevance for organizational performance” (Dutton & Ashford, 1993, p. 397) and that this strategic meaning exists on a symbolic as well as an instrumental dimension (Dutton & Ashford, 1993, p. 400).

Another of Dutton’s key contributions was the argument that a firm’s organizational environment influenced its perception and interpretation of issues. According to Dutton the: “meaning of an issue is not inherent in the issue itself, and that the organization’s internal environment has a major effect on the meanings that evolve” (Dutton & Jackson, 1987, p. 77). Dutton made a distinction between issues perceived to be either a “crisis” as opposed to a “non-crisis.” Dutton argued that firms allocated greater resources in the management of issues seen to be a crisis and that they also employed different frames to interpret crisis issues compared with those applied to issues seen as either non-crisis or opportunities (Dutton, 1986). The contention here is that a firm’s perception of issues is a function of cognition, and that this cognition itself assumes a strategic meaning where it informs decision-making.

Jackson and Dutton have analyzed the organizational implications of this for issue management. According to Jackson and Dutton:

for managers who use formal models of strategy formulation, identifying threats and opportunities is often a major objective of environmental scanning activities. Thus, managers who implement scanning systems ‘by the book’ institutionalize and legitimate these concepts for interpreting issues. (Jackson & Dutton, 1988, p. 370)

Within this, Jackson and Dutton have identified a bias among corporate managers towards the identification of threats over opportunities when assessing issues (Jackson & Dutton, 1988, p. 370), wherein “managers are more sensitive to

information that suggests the presence of a threat than they are to information that suggests the presence of an opportunity” (Jackson & Dutton, 1988, p. 384). Additionally, Jackson and Dutton proposed that the tendency of managers to identify more issues as threats than as opportunities is a learned trait which develops as a response to the fact that since it requires time for threat issues (especially novel threats) to impinge on a manager’s awareness, and that the negative impact of a threat tends to increase over time, it is in the interest of the manager to prioritize threat identification in order to enable a swifter response. As a result, ambiguous issues therefore tend to be identified more readily as threats (Jackson & Dutton, 1988, p. 385).

Porac and Thomas have subsequently identified the analysis of strategic cognition as a key stream in the research literature on cognition in management. Porac and Thomas define strategic cognition as being focused on the “linkages between ‘cognitive structures’ and decision processes in strategic management with respect to strategy formulation and implementation” (Porac & Thomas, 2002, p. 165). They define the objective of this research stream as the examination of the “blackbox” of cognitive models used by managers to interpret their business environments (Porac & Thomas, 2002, p. 165).

Issue Salience

Subsequent research has attempted to examine this blackbox in terms of a firm’s reaction to issues as the result of a process of cognition whereby the meaning of issues is perceived and interpreted. Following on Dutton’s work on strategic cognition, Bundy, Shropshire, and Buchholtz propose that a firm’s reaction to an issue is the result of a process of cognition. They maintain that: “reaction to an issue is not automated but, rather, driven by issue interpretation and perception” (Bundy et al., 2013, p. 356). This process of perception and interpretation is important because it mediates between the nature of the issue as an input and the action taken by the firm in response as an output (Bundy et al., 2013, p. 353). The result of this

mediating process determines the level of attention and priority which a firm will then assign to an issue (Bundy et al., 2013, p. 355).

This prioritization is based upon two criteria – the perception of issue salience with (1) firm identity and (2) strategic interests. Citing the importance of organizational identity for firms in order to express their uniqueness and differentiate themselves, Bundy, Shropshire, and Buchholtz argue that issues will be emphasized to the extent that they allow the firm an opportunity to express their identity (Bundy et al., 2013, p. 359). Similarly, issues which are seen to relate to the attainment of business goals are of obvious strategic interest to a firm (Bundy et al., 2013, p. 359).

For Bundy, Shropshire and Buchholtz:

organizational identity guides issue interpretation using an expressive logic, which is related to how the firm defines and displays conceptions of the self, while a firm’s strategic frame facilitates issue interpretation using an instrumental logic, which is predicated on the rational pursuit of organizational goals. (Bundy et al., 2013, p. 353)

Bundy, Shropshire, and Buchholtz have developed a classification and response schema for issues based on organizational logics and frames based upon these two distinct logics by which firms interpret issues: expressive (based upon organizational identity) and instrumental (based on organizational strategic objectives). Logical consistence with frames therefore shapes the perception of issue salience. An issue with expressive logic consistence: “is perceived as having bearing on or being material to the expression of an organization’s core values and beliefs” (Bundy et al., 2013, p. 355). By contrast, an issue with instrumental logic consistence: “is perceived as materially supporting or useful for the achievement of strategic goals” (Bundy et al., 2013, p. 355). The perception of an issue’s consistence may differ between the two logics, resulting in a conflict. Bundy, Shropshire, and Buchholtz categorize conflicts into two types: identity conflict and frame conflict. Identity conflict arises when a particular issue aligns with a company’s strategy, but is at odds with its identity. On the other hand, frame conflict takes place when an issue is inconsistent with a company’s strategy, but aligns with

its identity (Bundy et al., 2013, p. 365). Based on this distinction, Bundy, Shropshire, and Buchholtz propose a framework for a company's response to issues, which is influenced by three factors: the compatibility of the issue with the expressive and instrumental logics of the firm, the material significance of the response (either substantive or symbolic), and the form of the response (accommodative or defensive) (Bundy et al., 2013, p. 353).

Summary

A strategic approach to issue management emphasizes the detection and amelioration of external risks threatening to negatively impact the interests and plans of firms. This process is however not entirely objective. Although implemented in accordance with the objective procedures of strategic management, scholars have argued that, as an organizationally mediated process of cognition, it is important to recognize and understand how issue management is also shaped by subjectivity in assessing the salience of issues for firms. Consistent across this approach however is the centrality of the firm and the prioritization of its interests. This contrasts with the market and network approaches to issue management (see entries "Issue Management: Market Approach" and "Issue Management: Network Approach") which shifts the focus to issues within market and network relationships, respectively.

Johannesburg Declaration

Antonio Castrofino
Unitelma Sapienza University, Roma, Italy

Description

“The Johannesburg Declaration on sustainable development from our origins to the future” (Resolution A / CONF. 199/20, adopted on 4 September 2002) is the document drawn up and signed during the World Summit on Sustainable Development (WSSD) held in the capital of South Africa, Johannesburg, from August 26 to September 4, 2002.

The Declaration encompasses the will of the representatives of the population of the world to renew their commitment to sustainable development at all levels: local, national, and international. Conscious that the human being is facing

an important crossroads in its history, the 191 heads of state and government, with the participation of numerous representatives of local entities and more than 700 nongovernmental reviews, have announced that they want the burden of pursuing the objectives of sustainable development with responsibility towards one another, towards all living beings, and towards future generations.

In addition to the political declaration, the final document of the Johannesburg Summit is made up of an Action Plan, “Implementation Plan of the World Summit on Sustainable Development,” which has two main purposes: the first, to obtain the overcoming of the obstacles detected over the years by countries in the implementation of Agenda 21; the second, to underline the important role that the energy sector will have to play in the future and to relaunch the transformation phase to overcome the unsustainable production and consumption models adopted in the past.

The “Type II partnerships” were also presented during the Summit, new elements considered vital for the governance of sustainable development and for achieving the objectives of Agenda 21 (Doran 2002).

History of WSSD

The World Summit on Sustainable Development (WSSD) stems from the need to verify the results achieved, compared to the objectives set during

the Conference on Environment and Development held in Rio de Janeiro in 1992 and the progress of the eight objectives of the “Millennium Development Goals” of 2000.

Unfortunately, on this occasion, the few results achieved on a global scale had to be noted. Environmental degradation, in fact, continued its negative trend, with increasing CO₂ emissions from 1960 (316ppm) to 2001 (370ppm). The patterns of production and consumption, which had been proposed to change radically, but without results, and the data on poverty that continued to grow, also continued to remain unchanged.

Also for these reasons, world leaders seemed to want to relaunch their commitment, claiming to want to take care of the environment with greater responsibility. The Summit took place, however, amid the strong skepticism of observers, due to the evident difficulty of making the most industrialized states really active and interested in this cause. At the end of the agreement, in fact, it appeared immediately evident, although the intentions seemed to contain strong hope in terms of commitment to achieving the sustainable development objectives, that the signed Declaration would hardly have turned into concrete agreements.

The Johannesburg Summit had, however, in any case, the merit of creating an ever more important awareness and sharing of environmental problems between the world leaders and all the invited observers, in addition to having put this issue in greater light outside the purely scientific environment, giving it to the discussion of global civil society.

Content of the Political Declaration

The Johannesburg Declaration is divided into 37 points divided into 6 paragraphs: “From our origins to the Future,” “From Stockholm to Rio de Janeiro to Johannesburg,” “The challenges we face,” “Our commitment to sustainable development,” “Multilateralism is the future,” and “Making it happen!”.

Starting from the Stockholm Conference thirty years earlier, the importance of climate change is

recognized internally. In Rio de Janeiro in 1992 the United Nations Conference on Environment and Development had already reiterated the importance of protecting the environment in order to achieve environmental sustainability objectives and, on that occasion, the Agenda 21 was adopted, the Global Program and the Rio Declaration (Antich 2006). In Johannesburg, a broader consensus was achieved by connecting people with different visions of the path to be taken in the near future.

The Johannesburg Declaration recognizes the importance of overcoming poverty within the various societies that live on earth, as well as the need to reduce the gap between industrialized and developing countries. The proceeds of globalization, which leads faster to greater market integration, capital mobility, and investment flows, are not equally distributed and the populations living in the poorest countries are more vulnerable to climate change.

In the points of the Declaration, it is highlighted that the loss of biodiversity, increasingly put at risk by human activities of exploitation of the territories and by the growing global average temperatures, is a serious sign of environmental degradation, together with desertification to increasingly violent environmental disasters, unpredictable and frequent. Air, water, and sea pollution continues to endanger the lives of millions of people around the world.

The leaders present in Johannesburg, recognizing all this, therefore declared that they wanted to collaborate with each other by opening a constructive dialog between all the civilizations of the Planet, convinced of the indissolubility of human dignity, ready to act to overcome the difficulties of access to primary goods such as drinking water, a home, medical care, and food safety. To this end, in the Declaration, they seemed to agree in wanting to use the most modern technologies to bring, where there was not yet, development.

The leaders pledged to fight hunger, drugs, armed conflict, terrorism, intolerance, racism, and epidemics. They strive to achieve female emancipation and sexual equality.

It is recognized in the final part of the Declaration that humanity has the means to achieve the

objectives set and to this end, the developing countries are urged to maintain the commitments agreed at the international level. Indigenous people would also have played a very important role.

In the final points of the Declaration, large multinational companies are urged to maintain a responsible attitude towards the environment and social equity of the countries in which they legitimately operate. Commitments are promised about increasing job opportunities.

The leaders, in conclusion, declared that they wanted to proceed together, for human development and to achieve universal peace. They also declared that they need multilateral and international institutions that are democratic and accountable, recognizing a fundamental role of universal leadership at the United Nations to lead human civilization towards sustainable development goals.

Content of the “Plan of Implementation of the World Summit on Sustainable Development”

The Action Plan on Sustainable Development adopted in Johannesburg is annexed to the political declaration to try to define some priority objectives such as the fight against climate change as foreseen by the Rio Convention on climate change; ratification of the Kyoto Protocol (to countries that have not yet signed it); increase in the use of renewable energy sources; solidarity fund which provided for 0.7% of the GDP of rich countries to be allocated to projects in poor countries; halve by 2015 the number of people who do not have access to drinking water; and more integrated interaction between governments, citizens, and businesses to achieve sustainable development.

“Type II Partnerships”

Presented as elements of innovation at the Johannesburg Summit, the “Type II partnerships” are a democratic tool designed as useful for achieving the objectives of Agenda 21 (Hens and Nath

2003). The potential of the “Multi-stakeholder” partnerships is that of being able to overcome any states that they can find in intergovernmental diplomatic negotiation, thus increasing the possibility of achieving the objectives of sustainable development beyond mere bureaucracy. At the end of 2006, the United Nations registered 321 multi-stakeholder initiatives.

Key Issues

The solutions to the great climatic upheavals, which were already underway in 2002, did not succeed in unhinging a model of growth, production, and consumption, which was and is alive within contemporary society. In 2002 there was no real interest on the part of the industrialized countries to deal primarily with the environment and for this reason, the discussions that during the Summit on climate and environmental degradation seemed to stir again the spirits did not translate into concrete actions and commitments supported by binding agreements.

Future Directions

Climate summits after Johannesburg have increased in frequency even if, as of today, joint and concrete actions to combat global climate change have not yet been agreed. In fact, a binding agreement has not yet been reached for all the countries of the fundamental world to avoid the achievement of the nonreturn thresholds of CO₂eq concentration in the atmosphere to which the most validated scientific studies refer. In the near future, however, all world leaders will be called to take responsibility for acting for the good of all humanity and all forms of life on our Planet, through real commitments made during future mega-conferences (Seyfang 2003).

Summary

“The Johannesburg Declaration on Sustainable Development from our origins to the future”

(Resolution A / CONF. 199/20, adopted on 4 September 2002) is the document drawn up and signed during the World Summit on Sustainable Development (WSSD) held in the capital of South Africa, Johannesburg, from August 26 to September 4, 2002.

The Declaration stems from the desire to increasingly focus on the issue of sustainable development with a focus on every level of government, be it local, national, or international. Becoming aware that the human being is faced with an important crossroads in his history was certainly the reason that prompted the 191 heads of state and government (with the accession of numerous representatives of local authorities and more than 700 nongovernmental organizations) to announce that it intends to take on sustainable development goals, in collaboration and with renewed responsibility towards each other, with the critical awareness that it is necessary to preserve and protect ecosystems and all living beings, with an eye to future generations. Unfortunately, however, these objectives are still very far from being truly achieved and it will become increasingly important that these mega-conferences create concrete constraints to those who are committed to taking the path of change.

Political declaration of the WSSD

Definition/Description

The Johannesburg Declaration is the main political document that was adopted at the United Nations World Summit for Sustainable Development (WSSD), also known as the Rio+10 Earth Summit, which was held at Johannesburg, South Africa, in 2002 (UN 2002). The document is a follow-up to the Rio Declaration on sustainable development. It reassures the political commitment taken by states in the Rio Declaration in the area of state responsibility to promote sustainable development. The Rio+10 conference did an accent on both the socio-economic and the environmental aspect of sustainable development (Hens and Nath 2005), and both accents were incorporated in the Johannesburg Declaration.

The Johannesburg Declaration recognizes the structure-shaping role of globalization and highlights the importance of cooperation between developed and less developed countries (LDCs) in order to overcome both regional and global inequalities, and social and environmental challenges countries face (UN 2003). In this relation, a chapter of the declaration is dedicated to promoting another idea that multilateralism is the best feasible way to addressing the problems of climate change and global sustainable development (UN 2003).

It stresses on the importance of the introduction of transparent corporate social responsibility (UN 2003, art. 29).

The Declaration is a political document, which has no formal legally binding power. The

Declaration consists of 37 articles, divided into 4 sections (UN 2003). The representatives of member states signed the Johannesburg Declaration at the 17th plenary meeting of the World Summit on Sustainable Development, on 4 September 2002 (UN 2004).

History

World conferences are international conferences which are held under the auspices of the United Nations, involving broad participation of the world's states, concerned with global problems. As a rule such conferences, based on consensus, adopt declarations and programs of action (Nuscheler 2010). Declarations constitute statements which the UN considers to be of outstanding importance and consist of principles of a political or legal nature that signatories agree to and/or affirm through the declaration (Nuscheler 2010).

The Johannesburg Declaration is a part of the outcomes of a series of world conferences. The first conference was the United Nations Conference on Environment and Development (UNCED), also known as "Earth Summit," which was held at Rio de Janeiro, Brazil, from 3 to 14 June 1992. A number of documents emerged from the conference, such as the Rio Declaration on Environment and Development, and Agenda 21 – a comprehensive action plan for the sustainable development of the planet into the twenty-first century.

The next summit that aimed to continue the work of UNCED was the World Summit on Sustainable Development (WSSD). It was conducted in 2002 in Johannesburg, and the Johannesburg Declaration was the main political statement that originated from the WSSD, alongside the Johannesburg Plan for Implementation (La Viña et al. 2003).

The preparation of the text of the Johannesburg Declaration started a year before the WSSD (Gray 2003). In the process of preparation of the declaration, there had been differences over the binding nature of the document and over the strength of the obligations to be adopted. While some

countries stood for the adoption of concrete measures and timetables, others had remained weary of taking on new commitments (Gray 2003). However, the commitment to sustainable development was reconfirmed with the Johannesburg Declaration, and an emphasis on the importance of multilateral solutions for achieving not only the environmental goals but the social ones as well (Gray 2003).

Main Issues in the Johannesburg Declaration

The Declaration reaffirms the challenges that were outlined in the Rio Declaration on Environment and Development. It recognizes that "poverty eradication, changing consumption and production patterns, and protecting and managing the natural resource base for economic and social development are overarching objectives of, and essential requirements for sustainable development" (UN 2003). Global inequality and global environmental issues are stressed as major international problems.

By using the Rio Declaration and the principles developed in it, the Johannesburg Declaration puts a stress on social and economic development, as well as emphasizing on environmental protection issues (Hens and Nath 2005).

Among the conditions the Johannesburg Declaration states that are to be combatted are: chronic hunger, malnutrition, armed conflicts, organized crime, corruption, natural disasters, terrorism, intolerance, and endemic, communicable, and chronic diseases (UN 2003). It highlights the importance of including developing countries and small and island countries and helping them get an even chance at perceiving sustainable development (UN 2003).

The Declaration states that the private sector – large companies as well as SMEs – has a duty to contribute to the evolution of sustainable communities and societies. A stress on corporate accountability is put (UN 2003).

The last section of the Declaration puts a stress on the role of multilateralism as an approach to achieving sustainable development globally.

Therefore, improving efficiency of multilateral institutions is considered an essential factor (UN 2003).

Significance and Criticism

The Johannesburg Declaration has been considered one of the important political statements for sustainable development. The most important impact of such documents originates not so much from their binding effect but from their place as a document that promotes the world polity rationale for matters of both global and local scales (Givens 2017). As a result from the signing of the Johannesburg Declaration, the Johannesburg Plan of Implementation was adopted. It is added to the other key documents that followed the Rio de Janeiro Summit from 1992 (Rio Declaration, Agenda 21) (Hens and Nath 2005).

The Johannesburg Declaration is an important political statement for the promotion of sustainable development as it stresses on the importance of social and developmental issues and emphasizes on the multistakeholder approach to governance. The two political documents of the WSSD were also considered important progress in terms of corporate social responsibility and accountability (La Viña et al. 2003).

Despite the WSSD and its outcomes were considered to be significant steps in the formation of world polity of the process of sustainable development, they still faced some criticism. They were considered by some NGOs a compromise as opposed to adoption of legally binding conventions (La Viña et al. 2003). The WSSD as a whole faced severe critique of making inadequate progress on time-bound targets (La Viña et al. 2003).

The Political Declaration of the WSSD is a part of the so-called “type 1 outcomes” (Mehta 2003). The Declaration is noted to not set international principles that could be invoked in legal or political contexts (Mehta 2003). With this feature being typical for political documents of that type, the Declaration’s more general

contextualization puts it as a document that is seen as a foundation to the more detailed Plan of Implementation (Mehta 2003). Hens and Nath point out that it is very likely that the Johannesburg Declaration will not have the enduring impact or the intellectual sophistication and authority that the Rio Declaration of 1992 has (Hens and Nath 2005).

Summary

The World Summit for Sustainable Development was a follow-up event that marked the tenth anniversary of the Rio Conference on Environment and Development. The conference was held at Johannesburg, and the most important political document that was adopted there was the Johannesburg Declaration.

The Declaration is a document that reaffirms the political will of states to promote sustainable development in the spirit of the first Rio Conference from 1992. It puts a stronger emphasis on social and economic development compared to the Rio Declaration from 1992. It is a political statement that despite not being legally binding is of considerable de facto importance for the affirmation of a world polity on global issues in the field of sustainable development.

Definition/Description

The World Summit on Sustainable Development (WSSD) was a global United Nations (UN) forum that took place in Johannesburg between 26 August and 4 September 2002 (UN 2002a). The WSSD is a follow-up forum of the United Nations Conference on Environment and Development (UNCED) which took place in Rio de Janeiro in 1992. The Johannesburg conference aimed to provide a comprehensive 10-year review of progress made in implementing Agenda 21, the action plan adopted by the 1992 UNCED.

The WSSD was attended by 104 heads of state or heads of government. Overall, the forum had more than 21,000 participants, representing 191 national governments, different intergovernmental and nongovernmental organizations, the media, the private sector, and civil society (UN 2002b).

The topics which were discussed at the WSSD included issues such as water and sanitation, energy, health, agriculture and biodiversity (also known as WEHAB), achievement of poverty eradication, etc. (UN 2002b).

The Summit culminated in the adoption of the Johannesburg Declaration on Sustainable Development and the Johannesburg Plan of Implementation (JPOI), through which governments recommitted to the implementation of Agenda 21.

In December, the General Assembly endorsed the results from the WSSD. As a result of the recommendations that were made in the end of the Summit, the General Assembly appointed the timing of the United Nations Decade of Education for Sustainable Development to begin in 2005.

The WSSD’s Place in the Rio Process on Sustainable Development

The World Summit on Sustainable Development (Johannesburg, 26 August–4 September) is part of the United Nations sustainable development framework for global cooperation between states, nonstate actors, NGOs, etc. It is a follow-up and 10-year review to the United Nations Conference

on Environment and Development, also known as the Rio Conference. For this reason in literature the WSSD in Johannesburg is often called the Rio+10 (Hens and Nath 2005).

Background and Objectives

The World Summit on Sustainable Development was an international summit that is essentially a part of the Rio Process on Sustainable Development. The background of the WSSD lies in 1992 when the World Conference on Environment and Development (also known as the Rio Conference) was held. For this reason the 2002 Johannesburg Summit is also called Rio+10 (Hens and Nath 2005).

The original Rio Conference marked a new phase of development of relations between states, companies, nongovernmental organizations, and global civic society in terms of environmental responsibility and environmental protection. It addressed key social and environmental issues, and led to the adoption of crucial documents such as the United Nations Framework Convention on Climate Change (UNFCCC) and Agenda 21 (UN 1993).

The Rio+10 Summit was planned and organized as a continuation of the Rio dialog that started in 1992. The main purpose of the WSSD was to provide a forum hosted by the UN that would focus on discussion and furthering of the policies and commitments taken in Rio de Janeiro in 1992 (Hens and Nath 2005; Von Frantzius 2004). The necessity to adapt to the changing sociopolitical and ecological reality was the driving force behind the organization of the WSSD, and it was set to be one of the major United Nations events of the new millennium.

The main objectives of the WSSD were to reaffirm the commitments taken in Rio in 1992 and Doha in 2001, adopt new measures of implementation, and develop plans for action. With an ambitious plan in mind, organizers started negotiating on the texts of the documents to be adopted at the Summit in early 2002. However, the results from the Summit and the actual outcomes were not unilaterally accepted as successful (Mehta 2003; Von Frantzius 2004).

Commitments

The WSSD was a forum that aimed to reaffirm the commitments of the 1992 Rio Conference. The forum was a success in this manner. The WSSD's most important commitments were those that stressed on the socioeconomic aspects of sustainable development, affirming that this aspect of sustainable development is as equally important as the environmental responsibility aspect. At this Summit the government representatives agreed to enhance encouragement of industries and business to improve sustainable performance through adopting company policies and introducing voluntary initiatives and cooperation with public authorities and local communities (Verchick 2003).

Outcomes of the Summit have been separated in two categories: Type 1 Outcomes and Type 2 Outcomes (Von Frantzius 2004). The official political outcomes were categorized as the Type 1 Outcomes, and the Type 2 Outcomes constituted the voluntary nonbinding partnership initiatives between separate governments, business, NGOs, and civil society which sprung out of the communication between actors (Von Frantzius 2004).

The two most important documents that were adopted at the Johannesburg Summit were (UN 2002b):

1. The Johannesburg Declaration

The Johannesburg Declaration was the main political document that was adopted at the conference. It recognizes the structure-shaping role of globalization, and that the benefits and costs of globalization are unevenly distributed. It highlights the importance of cooperation between developed and less developed countries (LDCs) in order to overcome the regional and global inequalities, and the social and environmental challenges countries face. A significant aspect of the declaration is the commitment to multilateralism as an intergovernmental approach to sustainable development. It also includes commitments to engagement of various social actors, such as business, in achieving the common goals of sustainability (UN 2002b).

2. Johannesburg Plan of Implementation (JPOI)

The Plan of Implementations acknowledges the documents adopted at the 1992 Rio de Janeiro Conference as the stepping stones of all further action. The JPOI calls for the promotion of sustainable consumption and production by all countries and societies. Sustainable use of resources, focusing on education and development, and multistakeholder approach were brought up as key areas of work (UN 2002b).

The Plan specifies the role of developed countries as leaders in the adoption of sustainable development, and reaffirms the commitments of states that all countries should benefit from the process.

The Johannesburg Summit issued commitments in special areas, the so-called WEHAB (water, education, health, agriculture, and biodiversity). In the field of water and sanitation the countries committed to halve the proportion of people without access to safe drinking water and basic sanitation by 2015. In relation to health countries committed to achieve by 2020 minimization of adverse effects by the use of chemicals and implement better classification measures. Countries committed to reduce the rate of species loss and promote sustainable practices in biodiversity conservation and management (UN 2003b). The approach to education presented in the JPOI comprises of complex measures that parties should implement. On the global level, the Plan includes clauses aiming at the achievement of global goals for supporting the development of national programs and strategies to promote education within the context of the millennium development goals (MDGs). There is a focus on developing countries and regions. The Plan also includes education as a tool for promotion of sustainable practices such as ecotourism, health education, etc. (United Nations 2003b). The Plan of Implementation includes clauses on agriculture as well, with sustainable use of water and other resources being in the center. The Plan emphasizes on sustainable use of fisheries, and pleads for urgent development of “regional plans of action,

to put into effect the international plans of action of the Food and Agriculture Organization of the United Nations, in particular the International Plan of Action for the Management of Fishing Capacity” (UN 2003b).

Actors

The Johannesburg Summit gathered a wide spectrum of delegates that represented a variety of social actors. Like all global conferences organized by the UN, the main actors were considered to be representatives of nation-states and intergovernmental organizations. Important political dialog was conducted in traditional UN fashion. States coordinated their interests and policies in the field of sustainable development; they were key players in the adoption of the Rio+10 commitments. Important political statements were made by individual nation-states (for example, Russia and China announced the ratification of the Kyoto Protocol), and on collective level as well. Altogether, more than 8000 individuals from more than 900 organizations were represented at the Summit (UN 2002a).

However, the Johannesburg Summit included representatives not only of national governments, but delegates representing local public authorities as well. As author Robert Verchick qualified it, the Johannesburg Summit was the first global summit in which local authorities were so well represented (Verchick 2003). Their participation has been deemed ever more crucial, as local governments have been recognized as the organizational structures that would be directly implementing sustainable development policies in local communities. Local authority participation was present in the 1992 Rio Conference, and further enhanced in Johannesburg.

Continuing the practice of the first Rio conference, the Johannesburg Summit had a large number of nongovernmental organizations (NGOs) participating in the events. The NGOs were active participants in discussions and panels. NGO stands and platforms were situated in both in the main venue site – Sandton Convention Centre, and in smaller venues that were set up for the conference. A wide spectrum of NGOs was

present at the WSSD – from environmental organizations such as Greenpeace and World Wildlife Fund (WWF), to various industrial and business associations (Mehta 2003). Despite the large representation of NGOs and civil society structures, there were diverse reactions on the execution of the Summit (Mehta 2003).

The participation of companies and representatives of local and international business had already started picking up before the Johannesburg Summit. The conference however was attended by representatives of both major international companies from different industries, and smaller business as well. The participation and active position of business was considered a sign of the rising tendency of business interested in implementing sustainable practices of production and consumption (Mehta 2003).

Political Significance

The role of the Johannesburg Summit in the advancement of sustainable development has been considered not as effective as planned. However, there were some important tendencies that were manifested in Johannesburg.

The first tendency considered the general understanding of sustainable development. While the 1992 Rio Conference put the initial stress of sustainability on the environmental protection, it was at the Johannesburg Summit where the social part of sustainable development was stressed.

The second tendency, which was advanced in Johannesburg, was related to the procedural actions of actors. The tendency towards specification of different priority areas, and local communities, was manifested in both the wide representation of local governments, and the special discussions on the WEHAB themes. The Type 2 Outcomes of the Summit added more authority to the partnership initiatives approach which focuses on action-oriented cooperations between smaller groups of actors (Von Frantzius 2004).

WEHAB was given a special place at the Johannesburg Summit, and to this day the priority areas of water, education, health, agriculture, and biodiversity are considered key issues.

The Rio+10 Summit was also crucial for the promotion of the “Think global, act local” strategy and the advancement of the so-called Local Agenda 21 (Hens and Nath 2005).

Corporate Responsibility and Accountability

In terms of corporate social responsibility (CSR) and accountability, the Johannesburg Summit played a role of importance in furthering the conceptual and practical aspects of business engagement in sustainable development. Despite that CSR was not a separate topic of discussion, dialog over the optimal ways for promoting and achieving results in this field was present. However, the actual effects of the WSSD in terms of advancing the CSR notion were not as fruitful because corporate behavior and decision-making issues were hard to be discussed in an intergovernmental negotiations and decision-making framework. As La Vina, Hoff, and DeRose categorize it, the texts on corporate responsibility that were adopted could be considered as important but controversial achievements of the Summit (La Vina et al. 2003).

The Johannesburg Declaration included a text which stated that governments should “promote corporate responsibility and accountability and the exchange of best practices in the context of sustainable development” (UN 2003a). Article 29 states that the private sector should commit to corporate accountability in a transparent manner (United Nations 2003a). The Johannesburg Plan of Implementation included paragraphs that emphasized the role of companies in terms of enhancement of corporate environmental and social responsibility and accountability (UN 2003b), with practices in all levels of cooperation being pointed out in section III, paragraph 18 of the Plan (UN 2003b). Actions that were prescribed in the Plan were divided into four categories:

- Encouraging business to engage in voluntary initiatives, including environmental management systems, codes of conduct, certification, and public reporting on environmental and social issues (UN 2003b, III, paragraph 18, a))

- Encouraging dialog between enterprises and local communities (UN 2003b, III, paragraph 18, b))
- Encouraging financial institutions to include sustainable development considerations in decision-making (UN 2003b, III, paragraph 18, c))
- Encouraging the development of workplace-based partnerships and programs, including training and education programs (UN 2003b, III, paragraph 18, d))

The World Summit process identified not only what had to be done, but also who would do it, with many governments, nongovernmental organizations (NGOs), intergovernmental organizations, and the private sector launching partnership initiatives aimed at achieving sustainable development goals. In a series of partnership plenary sessions, participants focused on five priority areas for action – water and sanitation, energy, health, agriculture, and biodiversity, known as the WEHAB themes – as well as cross-sectoral issues and regional implementation. Four high-level round-table discussions and a multistakeholder event were also convened (Hens and Nath 2005).

Summary

The World Summit for Sustainable Development was a follow-up event that marked the tenth anniversary of the Rio Conference on Environment and Development. The conference was held at Johannesburg and the most important political document that was adopted there was the Johannesburg Declaration.

The World Summit process identified not only what had to be done, but also who would do it, with many governments, nongovernmental organizations (NGOs), intergovernmental organizations, and the private sector launching partnership initiatives aimed at achieving sustainable development goals. In a series of partnership plenary sessions, participants focused on five priority areas for action – water and sanitation, energy, health, agriculture, and biodiversity, known as

the WEHAB themes – as well as cross-sectoral issues and regional implementation. Four high-level round-table discussions and a multi-stakeholder event were also convened.

John Elkington

Antonio Castrofino

Unitelma Sapienza University, Rome, Italy

Basic Biographical Information

John Elkington is a British entrepreneur and academic. His research fields are corporate social responsibility and sustainable development. Born in Padworth in Berkshire, England, on June 23, 1949, he studied observed at Bryanston School (1966) and then graduated from the University of Essex, obtaining a Bachelor of Art in sociology and social psychology (1970). He completed the Master of Philosophy in urban and regional planning in 1974 at the University College of London.

Founder:

- Environmental Data Services (ENDS, 1978)
- Sustainability (1987–2008)
- Co-founder of Volans Ventures (from 2008 to today)

Senior consultant at the Resource Center for Business and Human Rights, member of the WWF Council of Ambassadors, professor at Cranfield University School of Management, Imperial College, and University College London.

John Elkington is responsible for the biennial “Project Breakthrough” program created in collaboration with the United Nations Global

Compact, dedicated to the opportunities offered by the market in the sector of exponential sustainability.

Major Contributions

John Elkington has spoken at over 1000 conferences, from the smallest ones to the Skoll World Forum and the World Economic Forum. He is the author of numerous books and over one hundred articles and reports. He also coined the terms “environmental excellence,” “green growth,” “green consumer,” “triple bottom line,” and “people, planet, and profit.”

Business

In 1980, John Elkington published his book “*The Ecology of Tomorrow's World: Industry's Environment*” in which he began to focus his attention on environmental issues as a fundamental center of world economic analysis.

In 1987, he wrote “*The Green Capitalists*,” with an additional chapter by Tom Burke, environmentalist, director of Green Alliance, president, and founding director of E3G. In this book, the two authors try to overturn the generalized vision of an industry too often in open conflict with what concerns the natural world and try to show how, instead, the attention of international industries to the environment is increasing. They explain that precisely this attention can ensure that industry and technology can be promoters of greater protection of environmental fragility. The book contains 10 steps that companies must follow to get more profits from environmental problems.

In 1989, in collaboration with Julia Hailes, British naturalist and writer, and Tom Burke, he wrote “*Green Pages: The Business of Saving the World*,” in which he projected in detail towards the future role that environmental issues would have had on European companies but also in the development of new technologies, in design, and how all this would necessarily have produced important influences within the political choices.

In 1991, John, in collaboration with Julia and Peter Knight, focused attention on companies

that, on the requests of consumers and shareholders, increasingly directed towards a conscious and environmentally conscious purchase, develop green processes. The book *"The Green Business Guide,"* in fact, thanks to the great experience of its author, is full of case studies and examines problems that concern all parts of a company, dealing with topics such as operational finance, legal and personnel services, research, transport, and office supplies.

In 1997, he wrote, *"Cannibals with Forks: The Triple Bottom Line of 21st Century Business"* in which he explains carefully how companies can and should all aspire to achieve the interconnected objectives of prosperity, environmental respect, and social equity, knowing that these objectives will be the future of the companies themselves.

In 2001, he wrote *"The Chrysalis Economy: How Citizen CEOs and Corporation Can Fuse Values and Value."* In this text, John Elkington shows the *"metamorphosis"* of the companies that have decided to take the road to reach the Caterpillar Economy for the Butterfly and Honeybee economies. John described the leaders and boards that he got to follow directly. At the same time, in a global economy that is experiencing transformations at very high speeds, he described the way of doing business changes, with companies anchored to old models that are transformed with new styles of corporate citizenship. In this book, John outlined the cultural perspective that will be needed in the future to achieve sustainability goals.

In 1997, he wrote *"Cannibals with Forks: The Triple Bottom Line of 21st Century Business"* in which he explained carefully how companies can and should all aspire to achieve the interconnected objectives of prosperity, environmental respect, and social equity, knowing that these objectives will be the future of the companies themselves.

In 2008, he wrote, in collaboration with Pamela Hartigan, Director of the Skoll Center for Social Entrepreneurship at Said Business School, University of Oxford, and founding partner of Volans Ventures, *"The Power of Unreasonable People: How Social Entrepreneurs Create Markets That Change the World."* This text is the collection of stories of "unconventional"

entrepreneurs thanks to which it was possible to overcome stringent economic, social, and environmental problems. In this text, the authors tried to describe the road towards which the risks and opportunities of the market will be directed soon.

"The Zeronauts Breaking the Sustainability Barrier"(2012) is the book with which John Elkington wanted to present a new generation of entrepreneurs and innovators who, having to face our present in an increasingly crisis-ridden planet, will be able to "break the barrier of sustainability" by overcoming it. The book addressed five key challenges: population growth, pandemics, poverty, pollution, and proliferation. The book introduced a five-step "Pathways to Zero" model: from discovery to the moment when the action becomes endemic in the economy.

In *"The Breakthrough Challenge: 10 Ways to Connect Today's Profits With Tomorrow's Bottom Line"* written in 2014, John Elkington, in collaboration with Jochen Zeitz, co-founder of The B Team and founder of the Zeitz Foundation for Intercultural Ecosphere Safety, started from the idea that the first and fundamental transformation that must necessarily take place in the business world is that concerning commerce. Attention to the intertwining of profits, the environment and society will be fundamental to create lasting success. John drew companies' attention to redefining the bottom line to take into account all real long-term costs across the supply chain. To achieve this, leaders must rethink everything. This book guides the leaders to achieve a true transformation and repositions the definition of profitability on the lasting well-being of people and the network, without which the lasting success of their activities is not possible.

Consumer and Lifestyle

In 1988, John Elkington published in collaboration with Julia Hailes his book *"The Green Consumer Guide: From Shampoo to Champagne: High-Street Shopping for a Better Environment"* to sensitize readers about the difference between products. In this approach, the two authors, in 1989 wrote *"Green Consumer Guide."* This writing was conceived as a true guide in a conscious

daily purchase. The two authors examined a wide range of products, advising against some products that are harmful to the environment, and referred to valid and interesting ecological alternatives respectful of nature. The book focused on products such as detergents, batteries, bulbs, sprays, but at the same time, it also dealt with an important topic such as “ecological” tourism and “green” gifts.

Also in collaboration with Julia Hailes, in the following years, John Elkington wrote: “*The Green Consumer’s Supermarket Shopping Guide*” (1989) and “*The Young Green Consumer’s Guide*” (1990), continuing to deepen the theme of informed purchases.

In 1992, the two authors wrote “*Holidays That Don’t Cost the Earth*.” This text highlighted the issue of sustainable tourism and advised hikers’ places and holidays that do not harm the planet. In the book, there is also a survey between Tour Operators and Ecotourism Companies.

At the gates of the new millennium, John Elkington and Julia Hailes wrote: “*Manual 2000*” (1998), a book that, starting from the analysis of the speed with which science and technology were leading man at the gates of the new millennium, asked questions where this speed will lead us and if all that will be achieved will be positive for humanity. John then tried to indicate what is more right and what is not for him, explaining what the moral, social, and environmental issues that will have to be addressed will be. The book is also a guide for the consumer, listing the options available, to understand what is convenient to buy from food to the personal computer.

John Elkington wrote the true guide to food trends of contemporary man in 2001 when he published “*The New Foods Guide: Gene Food Consumer Guide*.” Accompanying the consumer among the products of the supermarket, this book is designed to indicate which products are impacting our health today, in the manifestation of certain diseases, new organic foods, reading the labels on products, GMOs, really knowing which brands we are buying. The book contains a real manifesto about what the food industry should do

and indicates which companies are already heading in the right direction.

Science and Technology

In 1984, Elkington wrote “*Sun Traps: The Renewable Energy Forecast*.” Starting from an analysis of solar, wind, and energy released by the movement of the waves, he analyzed the scenario of renewable energies by comparing them with nuclear energy and the energy produced from fossil sources.

On the impact that pollution has on the human being, he wrote in 1985 “*The Poisoned Womb: Human Reproduction in a Polluted World*” in which he dealt with the topic of reproduction, human fetal development in an increasingly polluted world and which therefore can affect diseases and malformations, and “*The Gene Factory: Inside the Genetic and Biotechnology Business Revolution*” in which, in addition to highlighting the discoveries that science has made in the medical field, it also illustrates what risks are faced if a “war of germs.”

Other

In 1990, Elkington wrote “*A Year in the Greenhouse: An Environmental Diary*.” In this book, he told what appeared to be an ecological awakening and an awareness by world leaders of environmental problems, the year 1989. In this year, the Greens in Great Britain have had their first success with the European elections. The industry at the same time recognized a growing role for the green consumer and all the mass media, from newspapers to televisions, raised green issues. This book is also a story of the author’s commitment to the environmental world.

In 2015, John Elkington collaborated on the book by Doug Miller, founder and president of the global research consultancy firm GlobeScan Inc., “*Can the World Be Wrong?: Where Global Public Opinion Says We’re Headed*.” The book, which collects 30 global opinion polls on various topics including economics, globalization, and geopolitics, through public opinion trends over the past decade in 20 countries seeks to trace a line of future global trends.

The Triple Bottom Line

The environment, society, and finance (profit) are intertwined. To be able to create the conditions for sustainable development, the weight of each element must be put back in the right order. Represented in concentric circles, the first and largest circle is that of the environment which necessarily contains everything else since Planet Earth is the basis for building our society. The latter is the second circle and contains within itself the third circle, namely that of finance. The structure thus defined redesigns the right position of every single element and only by respecting this structure can true Elkington achieve truly sustainable development.

Revised 25 years later, the Triple Bottom Line (Fig. 1) is a sustainability framework that examines a company's social, environmental, and economic impact. As explained by "The Economist" magazine, only the company that takes into account the TBL considers the full cost of its business.

Honors and Awards

- 1973: University College London, travel fellowship to the USA
 - 1981: Winston Churchill Memorial Fellowship
 - 1989: United Nations Global 500 Roll of Honour, alongside Julia Hailes
 - 2006: 3-year, \$1 million grant from the Skoll Foundation for Social Entrepreneurship, which covered work both at SustainAbility and later at Volans
 - 2008: Fast Company Social Capitalist Award (on behalf of SustainAbility)
 - 2010: American Society for Quality Spencer Hutchens, Jr. Medal for champions of quality and social responsibility
 - 2011: Rockefeller Foundation Bellagio Fellowship, used to write part of *The Zeronauts*
 - 2013: Inducted into the Sustainability Hall of Fame by The International Society of Sustainability Professionals (ISSP) in honor of "extraordinary contribution" to the field through research, publication, teaching, and innovation
 - 2014: Honorary Doctorate, University of Essex
- Over time he has received many other awards:
- In 2004, BusinessWeek described him as "a dean of the corporate responsibility movement for three decades."
 - In 2008, The Evening Standard named him among the "1000 Most Influential People" in London, describing him as "a true green business guru," and as "an evangelist for corporate social and environmental responsibility long before it was fashionable."
 - In 2009, a CSR International survey of the Top 100 CSR leaders placed him

John Elkington,
Fig. 1 The triple
bottom line

fourth: after Al Gore, Barack Obama, and the late Anita Roddick of the Body Shop, and alongside Muhammad Yunus of the Grameen Bank.

- In 2011, he was named among the “100 Global Sustain Ability Leaders for 2011” by ABC Carbon and the SustainAbility (nothing to do with SustainAbility) Showcase Asia, based on nominations and recommendations received from around the world.

John Gerard Ruggie and the UN Guiding Principles on Business and Human Rights

Nelarine Cornelius¹ and James Wallace²

¹School of Business and Management, Queen Mary, University of London, London, UK

²Hertfordshire Business School, University of Hertfordshire, Hatfield, Hertfordshire, UK

Synonyms

Corporate responsibility (management); Corporate Social Responsibility (CSR); CSR management; Human rights; UN Guiding Principles of Business and Management

Definition

The UN Guiding Principles on Business and Human Rights were formalized and published in 2011 (United Nations 2021). Financially oriented UN Principles (first agreed in 1992) were revised and refined: the UN Principles for Responsible Investment, the UN Principles for

Sustainable Insurance, and the UN Principles for Sustainable Banking (United Nations 2022). The development of this group of principles is of note, as it represents a shift from a focus on national governments, to a shift toward business, especially international business, the impact that business activity can have on the environment and community development, and the role of government in safeguarding the latter. Ruggie, The UN and scholars in the field continue to develop Ruggie's principles, especially regarding how best to improve accountability for violations (Khoury and White 2015; Ruggie et al. 2021; Taylor 2021; United Nations 2021) given the demands of the Ruggie Principles and the economic and political power of corporations.

Introduction

John Ruggie (1944–2021) was a full professor in both School of Law and Kennedy School of Government at Harvard University. These posts are indicative of the interests held by Ruggie, but also the cognate disciplines that he was able to draw from. Ruggie's earlier work on territoriality, globalization, and accountability helped to lay the foundations for his work with the UN. It is of note the earliest work on human rights, the development of which was led by Eleanor Roosevelt. Roosevelt was the first Chairperson on the Commission for Human Rights, and she played a leading role in drafting the 1948 Universal Declaration of Human Rights (United Nations 1948, 2022). Of note also is Roosevelt's establishment of a subcommission, on the Status of Women which included colleagues from Lebanon, Poland, Denmark, Dominican Republic, and India (United Nations 2022). The importance of laying the foundations for women's development and women's equality was thus incorporated into the original draft of the Universal Declaration, and was followed later by the UN Gender Equality and Gender Inequality indices (Seth 2009; United Nations 2022); updates to the UN's position of rights meant that the original declaration was a living declaration that could evolve over time.

The Path Toward Business and Management CSR and Corporate Accountability

Ruggie's interests resonate with Article 30 of the Universal Declaration "*Nothing in this Declaration may be interpreted as implying for any State, group or person any right to engage in any activity or to perform any act aimed at the destruction of any of the rights and freedoms set forth herein.*" (United Nations 2022). In 2011, the "*protect, respect, remedy*" rational that underpins the John Ruggie Framework on Business and Human Rights, which became the UN Guiding Principles on Business and Human Rights, adds to the original UN Human Rights declaration by highlighting the ethical responsibilities not only of nation states, but of business.

As early as the 1950s, Howard Bowen (2013) had developed ideas on corporate social responsibility, captured in his book "*The Social Responsibility of the Businessmen.*" Many well-known CSR frameworks exist, but the enduring challenge was to embed CSR into the formal governance of the corporation, not as a standalone, peripheral activity with limited corporate accountability. Increasing interest in the impact of business on the environment, climate change, and local communities in the latter part of the 1990s onward, reaching a peak with international climate change commitments by national governments (e.g., UN Climate Change national governments meeting, COP 11 Kyoto, (UNFCCC 1997), protocol agreed and ratified in 2005), created the ideal moment to focus again on corporations and the potentially negative impacts of their activities.

Ruggie's appointment by the United Nations as a Special Envoy afforded him the opportunity to draw on his expertise, consult widely, and then draft recommendations to present to the UN on how best to create a contemporary, global position on the duties and responsibilities of corporations (Ruggie 1983; 2008a, 2008b, 2009).

Ruggie developed 31 directives, framed in three main pillars: the state duty to protect against human rights abuses, the corporate responsibility to respect human rights, and the need to help

victims achieve remedy. These three pillars recommend that companies demonstrate and implement respect for human rights, take measures such as make a public commitment, and identify, prevent, mitigate, and account for damage. Ruggie continued to hone and refine the application of these pillars for many years and violations.

Summary

The development of greater business accountability with regard to human rights owes a great debt to the foresight and distinctive intellectual interests of John Ruggie. Earlier work had made clear the nature of human rights but less so the critical and central role of business. Ruggie's 31 directives highlighted not only the moral and legal responsibilities of business but also the role of the state in ensuring corporate accountability and legal compliance.

[Continuous improvement](#)

Definition

Kaizen is a Japanese word (改善) for describing “continuous improvement.” This word comprises two themes: *kai* (改) meaning reform, change, modify, examine, inspect; and *zen* (善) meaning virtuous, good, and goodness (Macpherson et al. 2015). Together they mean a change for the better, or in other words: a process of incremental improvements (Liker 2004). Kaizen as a word in the English language was introduced into the Oxford Dictionary in 1993 (Sheridan 1997). There it is defined as the practice aimed at improving the company performance (operation way) done by continuously improving. In this meaning the business aspect is highlighted, while it can also concern daily life by contributing to greater self-reliance and self-control (Pinto et al. 2018). More broadly, the improvement refers to workplace, personal life, home life, and social life (Imai 1986).

The concept assumes continuous, ongoing, and gradual improvement. The change usually happens due to undertaking small steps producing small effects. Therefore, kaizen is opposed to the notion of types of innovation, which are understood as significant, breakthrough change, usually occurring only once in a given period.

The key features of kaizen are: continuous efforts toward better quality; incremental, but not radical change; requiring participation and involvement of all workers from different managerial levels (Brunet and New 2003). Kaizen characterizes the work of small groups aimed at problem solving, analyzing data, and thanks to open discussion, leading to new solutions.

History

Due to the Japanese origin, *kaizen* is perceived as an oriental invention. However, it has roots in Western scientific management. The origin of kaizen is located within the training program “*Training Within Industry*” (TWI). In this program, two topics were closely related to the current understanding of kaizen: *Job Methods* and *learn by doing*. Analysis of earlier works on the TWI program from 1943 point out its confusingly similar workshop topics, such as: “Job Methods will help supervisors to make many small improvements on the job they are closest to” (Huntzinger 2002). The links between TWI and kaizen demonstrates TWI materials found in

Toyota training documents (Huntzinger 2002). As Imai and Liker described kaizen, it became a key pillar for the Toyota Production System and TQM commonly used by international and national companies. This is how it came back to the USA and other Western countries.

Key Issues

Kaizen is one of the 14 principles of quality management (see ► [“Quality Management”](#)) coined by E. Deming (2000): “Improve constantly and forever the system of production and service, to improve quality and productivity, and thus constantly decrease costs.” Deming points out that improvement requires to possess knowledge about a studied area linking it with the need to learn. Kaizen is also a part of Toyota Way’s Principles where it is related to learning: “become a learning organization through relentless reflection (hansei) and continuous improvement (kaizen)” (Liker 2004). It embraces an attitude of self-reflection and self-criticism, which are necessary according to Liker to make improvements.

Due to its nature, kaizen allows workers to achieve self-actualization. Searching for improvements requires employees’ involvement and intelligence. Therefore, the kaizen’s idea is referred to works of scholars representing Human Relations School, such as: E. Mayo, A. Maslow, D. McGregor, Ch. Argyris and F. Herzberg (Brunet and New 2003).

Kaizen is also an umbrella term. Imai literally describes it as a practice overarching many quality and lean management systems and methods, including: Total Productive Maintenance, Just-in-Time, Kanban, Quality Control Circles, 5-why, Total quality control (TQC)/total quality management (TQM), a just-in-time (JIT), Toyota Production System, Total productive maintenance (TPM), policy deployment, a suggestion system, and small-group activities (Imai 1986, 2012).

The main principles associated with kaizen are: program 5S; focusing on processes, operational standards, and quality; active participation; strategic planning; using problem solving techniques; and education (Suárez-Barraza et al. 2019).

According to the results of a study conducted among Japanese workers, because its main idea is to steadily introduce small changes, kaizen is more process-oriented than result-oriented. The organization can promote kaizen among workers through education and campaigns. Kaizen is not homogeneously perceived within one company. Kaizen practice depends on headquarter–subsidiary relationships and is affected by a business culture. It also means that kaizen is not a bottom-up activity, but also results from managerial orientation. Thanks to contrasting bottom-up perspective with top-down, it allows the development of a wider organizational view (Macpherson et al. 2015).

Kaizen requires conditions related to individual traits and organizational settings. The first group comprises attitude toward problem solving, knowledge about problem-solving tools, and readiness to change. The second group refers to supporting organization environment including control and monitoring mechanisms during introducing a change (Kiran 2017).

Kaizen is not only beneficial on a company level, but also on a personal one. Adapting kaizen step by step helps to improve quality, develop new products/services. From a personal perspective, as small changes do not require a lot of effort and do not trigger fear toward change, kaizen leads to morale increase and reduces healthcare expenses due to introducing a non-stressful way of improvement (Maurer and Hirschman 2013).

A version of kaizen aimed at providing quick improvement is called kaizen blitz. The features of this approach include to analyze a specific problem by a team comprising 6–12 members from different managerial functions and levels, who within 3–5 days, propose a new solution (Oakland 2014).

Future Directions

Kaizen’s popularity and potential popularized its use in other business sector than production. It can be found in improving teaching activities (Kregel 2019), education institutions (Suárez-Barraza et al. 2019), and healthcare (Grabán 2018;

Sommer and Blumenthal 2019). These examples demonstrate a spread of kaizen philosophy in services where creativity for improvement is required.

The next development represents merging kaizen with other quality or lean management techniques. Example include gemba-kaizen (Cherrafi et al. 2019). In the Japanese language, gemba literally means a place where something happens (Imai 2012); thus a joint phrase expresses the idea of improvement directly at the workplace.

The culture-dependent successful usage of kaizen evokes studies on its introduction in different national cultural settings. The reports of using kaizen in Asia and Western countries demonstrate successful application. In Africa, a late adopter, kaizen training leads to better enterprise performance (Sonobe 2018).

Kaizen is mainly interpreted as a practice and practical results are very often described, but the theoretical foundations are missing (Carnerud et al. 2018). The lack of a theoretical framework may cause problems with choosing kaizen as a research subject. Moreover, kaizen is very often treated very generally as a business philosophy (a never-ending journey toward excellence) or more specifically as a way of introducing improvements at the workplace.

Kaizen was proved to be successful for improvement in different business and functions. Also it can be linked with sustainability activities within the company (Glover et al. 2011).

2018 United Nations Climate Change Conference; Conference of the Parties to the United Nations Framework Convention on Climate Change (COP24); Katowice climate change conference

Definition

Katowice climate negotiations (COP24) were the first negotiations after the Climate Change Conference in Paris (COP21). Given the history of climate negotiations, the scope and roles of the parties have changed. COP24 was the first meeting under the presidency of a Small Island State. By the time of the Katowice conference, the international climate negotiations had shifted from a top-down approach towards a bottom-up approach. Instead of UNFCCC, countries set up their own targets and goals. The expectations

of the meeting were relatively high after the successful meeting in Paris. Developing countries did not receive a clear commitment of extra financial resources in addition to official development assistance. However, the “rulebook” for implementing the 2015 Paris agreement was further developed.

Introduction

In the history of climate negotiations, three issues shaped the discussions. First, climate change is a global problem that affects all economies around the world. Second, the parties have different historical responsibilities for greenhouse gas emissions. Third, the lack of hierarchy and sanctions in decentralized world politics makes enforcement of a global climate agreement difficult.

The expectations of the Katowice meeting were relatively high after the successful meeting in Paris. The Katowice negotiations were supposed to encourage commitments to the Paris agreement and stress the urgency of enhanced ambition towards mitigation actions with adequate financing, technology, and capacity-building support.

The Intergovernmental Panel on Climate Change (IPCC) highlights the significance of limiting the warming to 1.5 °C and the need to maintain a strong commitment to the Paris Agreement's aims. The Katowice Climate Conference (COP24) was the first negotiations after the Climate Change Conference in Paris (COP21), where the Paris Climate Agreement was accepted. In the conference hosted in Katowice, 12,810 parties were registered, including organizations such as United Nations Secretariat units and bodies, intergovernmental and non-governmental organizations, and specialized agencies and organizations. These participants formed groups according to their interests. All parties were expected to communicate and undertake ambitious efforts within the reports that are called the Nationally Determined Contributions (NDC) that are part of the global attempt towards climate change mitigation.

The Katowice conference was expected to continue the progress started in Paris, including clarifying the Intended Nationally Determined Contributions (INDC). However, the concern of developing countries is that a mitigation-centric (NDC) regime will push adaptation, finance, technology transfer, and capacity building for developing countries further and further into the background.

History

2015: Paris

Since the Kyoto Protocol, the global community has been trying to negotiate a mutual approach to mitigate climate change. The most comprehensive global climate change agreement was negotiated in 2015 at COP21 in Paris. It brought all nations into a shared struggle towards climate change. The Paris Agreement is based on a pledge and review scheme that requires all parties to enforce their most ambitious policies through NDCs and to extend these efforts in the future.

2016: Marrakesh

The COP22 in Marrakesh continued the progress started in Paris by establishing a rulebook for the implementation of the Agreement, based on transparency and accountability. The parties adopted 35 decisions, mostly related to the implementation of the Paris Agreement. The involvement of non-state actors was also discussed. Outside the formal negotiations, groups aiming to switch to 100% renewable energy and decarbonize the economies were formed.

2017: Bonn

The COP23 climate summit was the first to be presided by a small island, although the vulnerability of small islands to climate change has been known for a long time. The main objective of the Bonn COP23 was to outline a rulebook for implementing the practical issues of the Paris Agreement. A preference for the EU was to outline the details in the rulebook and assure that the deadline in 2018 is not missed.

One of the most significant accomplishments of the COP23 was the launch of the Talanoa Dialogue, which stands for open and inclusive exchange. This dialogue had its premiere in January 2018 with the aim of investigating the level of nationally determined contributions (NDCs). The financial commitments and transparency of financial flows under the Paris Agreement were debated again in Bonn (Dröge and Rattani 2018).

COP23 in Bonn focused more on specific methodological issues as countries proceeded to debate the technical details of the agreement. The major contribution was the display of the “Powering Past Coal Alliance,” led by the UK and Canada. This alliance gathered more than 20 countries in addition to subnational parties. However, two issues raised uncertainty. Developed countries had not yet received the expected amount of finance (100bn\$ per year by 2020) settled in 2009 in Copenhagen. Further, the Doha Amendment, a second commitment period of the Kyoto Protocol, was left without support and had not become widely ratified among the parties.

The UN met in December 2019 in Chile to assess the technical details of the Paris rulebook and settle future emission reduction obligations. New targets for 2030 and beyond were discussed.

Roles of the Parties in the Negotiations

The UN tradition is to group parties, each represented by national delegations, according to their regions and shared interests. Traditionally, the EU has played a leading role in climate negotiations (Dröge and Rattani 2018).

Alliance of Small Island States (AOSIS) members have been demanding a binding target and requesting developing countries to take responsibility. As the most vulnerable countries to climate change, they have raised specific issues of predominant concern to them (Dröge and Rattani 2019).

COP24 was the first meeting under the presidency of a small island state. A Least Developed Countries Work Program was established to focus on the distinct demands and requirements of the

Least Developed Countries, noting the particular support needs and promoting awareness. The program highlighted the implementation of the elements instead of merely supporting the planning process in least developed countries.

Least Developed Countries require support for implementing decisions. The Katowice decisions encourage parties of developed countries to continue finance adaptation activities along with transparent and reliable data on the provided climate finance. COP24 calls for balanced financing between mitigation and adaptation as well as developments in relevant organizations and institutions for mobilizing the finance. India and African countries, for example, have expressed concerns about the sufficiency of the funding promised to the Least Developed Countries for mitigation and adaptation. A platform for a dialogue between parties and non-party stakeholders was founded, called the Talanoa Dialogue.

After Paris Agreement

The Paris Agreement resulted in three different structural transformations in global climate politics. First, this global effort led to reduced disparity between developed and developing countries, exempting the poorest countries from requirements to mitigate climate change. Second, the Paris Agreement has shifted from the Kyoto Protocol's top-down "targets and timetables" to a bottom-up "pledge and review" process. This has shifted the focus towards national climate policy. Third, the Paris Agreement represents "hybrid multilateralism," which focuses not only on governmental actions but also on climate action by non-governmental actors and businesses (Andonova et al. 2017; Bäckstrand et al. 2017). The most significant actions for climate change mitigation are expected from national and local governments around the world with help from the private sector, scientists, and engineers.

After Paris, the interest has moved towards reporting emissions and the quality of the plans. The Paris Agreement was a positive surprise with high ambition. It aims to prevent warming over 1.5 °C. Parties released their NDCs. These

contributions are expected to guide the national climate policy and also form a base for the new climate regime (UNFCCC 2016). However, national pledges fall well below the actions needed to meet those ambitious targets. Many large emitters are not likely to fulfil their self-set obligations, according to Climate Action Tracker (2021).

However, one of the biggest emitters, China, pledged in Paris to peak greenhouse gas emissions by 2030. The country is likely to achieve the target due to policies already in place without placing any new measures. This has raised questions as to whether the country should set a more meaningful climate target. European leaders have been fervently debating the level of fair emission reductions of the EU since the Paris Agreement. Some nations demanded more ambitious targets. "It is plain we are way off course," said António Guterres, the secretary general of the United Nations, in Katowice. "We are still not doing enough, nor moving fast enough, to prevent irreversible and catastrophic climate disruption."

In June 2018, European officials set more ambitious targets for renewable power and energy efficiency (European Union 2019). Still, there are plenty of obstacles. For example, Poland is currently constructing more coal plants (WNN 2020). Many of the pledges lack information on the specific policies to meet the ambitious targets. Further, official mechanisms for quantifying progress do not exist. Making the pledges more transparent could lead to more pressure on the countries, but it is up to national and local governments to agree on firmer actions. Many countries have strengthened their pledges by 2020, including the EU. Critics of Paris are stating that the agreement reflects little more than what individual countries were likely to do anyway (Somerville 2020).

The Katowice climate negotiations were expected to blaze the trail towards 2020 and come up with clear guidelines for national pledges and policies for increased transparency. This would assist in the evaluation of the countries' improvement. Some developing countries stated the limited access to technology for measuring emissions and the need for wider flexibility in reporting and verifying their improvements (COP24 2020).

Mission of the COP24

COP24 was organized in Katowice 2018 with the ambitious intention of adopting the practical details of the guidelines of the Paris Climate Change Agreement. The focus areas included adaptation to climate change impacts, ambitious emission reductions, and support for developing countries. This support is to be provided in the form of technology, capacity building, and funding. One of the objectives was to create a platform for a Talanoa dialogue (COP24 2020).

Contributions in Terms of Emission Reductions

Katowice negotiations adopted a vigorous set of guidelines for carrying out the 2015 Paris Climate Change Agreement. The Katowice Rulebook was not able to address how global climate policy should be conducted and the actual climate measures implemented. The agreed Katowice Climate Package promotes international cooperation and encourages greater ambition towards climate change mitigation. The deadline for the countries' self-set targets was 2020. Thereafter, countries were expected to affirm new and much tougher targets.

During the Katowice negotiations, countries resolved most of the problematic aspects of the Paris Agreement "rulebook". This included measuring, reporting on, and verifying their emissions-cutting efforts. This makes all countries responsible for holding on to their commitments (CarbonBrief 2019).

Most importantly, COP24 raised the question of the information required by article 9.5 of the Paris Agreement, which concerns mobilization of climate finance to developing countries. The recognition of such required information was found at COP22, and the process was completed by COP24 (CarbonBrief 2019).

Carbon capture was also on the table and received long-term political support. The predictable and confident support for carbon capture storage as a mitigation option in addition to other low carbon emission technologies was

welcomed. This support is provided through international funding mechanisms and private-public partnerships. Further, a declaration on "Forest for climate" was founded. This declaration highlighted the important role of forests in reaching the Paris Agreement goals. However, the declaration was criticized for encouraging delaying actions to reduce emissions. Others were concerned about the lack of any concrete short-term targets (CarbonBrief 2019).

The COP24 in Katowice, Poland, introduced a comprehensive "rulebook" revealing the details of the implementation of the Paris Agreement. Nations agreed on uniform rules for measuring and reporting their own performance in cutting emissions. The negotiations on these details turned out to be more challenging than those leading to the Paris Agreement. Excluding the rulebook marks, the results from COP24 were less ambitious (CarbonBrief 2019).

Other Contributions

One of the main tasks for climate negotiations is to provide dialogue between different actors to raise the ambition towards more effective implementation of climate change mitigation goals and strategies. One of the most crucial questions is how the Paris Agreement can encourage countries to take more ambitious actions in the future.

A deciding phase in the rulebook negotiations was to clarify the differentiated responsibilities of the countries. This encompasses the differentiation of obligations along the common but differentiated principle, including the hazardous impacts derived from rising greenhouse gas levels. In particular, developing countries have called for differentiated rules for developed countries in terms of financial commitments. Notably, China also turned to support differentiation (CarbonBrief 2019).

COP24 revealed a Local Communities and Indigenous Peoples Platform that invites parties to empower the local communities. This platform aims to improve equality and not endanger the livelihood of unprivileged people. The impact of energy transition on workers and their

communities was also debated. Climate decisions require enough support in technology transfer and capacity building. This was recognized in a decision by COP24 on enhancing climate technology development and transfer through a technology mechanism (CarbonBrief 2019).

One of the focus areas debated was finance. Even though commitments on funding for developing countries are sufficient, the impacts of this funding on the sustainable development objectives of the country are not well understood. COP24 proposed a commitment of USD 100 billion per year by 2020 for developing countries.

Financing Issues

Developing countries did not receive a clear commitment to new financial resources in addition to official development assistance. The finances provided should be allocated to loss and damage. However, the definition of climate finance was narrowed to exclude commercial loans and non-financial efforts, such as capacity building or technology transfer. Reporting on the grant equivalent value of all finances provided has also become mandatory (CarbonBrief 2019).

Two challenges regarding finance were the coverage of sectors and double counting. Primary finance focusing only on a new climate activity is one option to avoid double counting. One of the issues discussed was accounting and reporting climate finance. Developed countries should report rigorously on climate finance provided to developing countries. United Nations agencies and financial institutions should describe how their development assistance and climate finance program are consistent with newly available scientific information.

COP24 resolved that “parties shall apply the accounting guidance to their second and subsequent NDCs and account for their NDCs in their biennial transparency reports under Article 13” and discussed the following issues related to climate finance:

- Long-term climate finance
- Issues with the Strategic Climate Fund (SCF)

- The Green Climate Fund (GCF)
- The Global Environment Facility (GEF)
- The commitment of the parties to Article 9, paragraph 5 of the Paris Agreement

In terms of long-term finance, the COP24 decided to mobilize USD 100 billion annually by 2020. However, a binding long-term financial goal was not agreed upon. COP24 did not address the issue of determining the key components of climate finance (Alexandraki 2019). Future climate negotiations will likely include a discussion on the effectiveness of climate finance, such as the outcome of the funding mobilized to developing countries.

Transparency and markets could not fully agree during COP24. The parties did not reach consensus on rules for Article 6 on market-based approaches and therefore decided to postpone this decision to COP25 (CarbonBrief 2019).

Summary

The Katowice conference was expected to continue the progress started in Paris. This 2018 COP24 was the first meeting presided by a small island state and was organized with the main purpose of adopting the implementation guidelines of the Paris Climate Change Agreement. The expectations after the historical meeting in Paris were relatively high. Katowice negotiations highlighted emission reductions, mobilizing finance, and sustainability. The main results of the meeting included the decisions on measuring, reporting, and verifying emissions-cutting efforts implemented by the parties. However, developing countries did not receive a binding long-term financial commitment. This raises concerns about whether those countries are willing to strengthen their INDCs in the future. Finance, the rate of deployment, and political uncertainty were among the topics of discussion. By 2020, the parties were expected to meet their emissions commitments and state new objectives for 2030 that would actualize the scientific advice provided after the final elements of the Paris rulebook were agreed upon in 2019.

Corporate Governance (CG); Corporate Social Responsibility (CSR); King Reports

Definition

The purpose of the chapter is to investigate the “state of the art” on sustainability reporting, in South Africa. Such country represents a worldwide *unicum* as a consequence of the publication and adoption of the King Reports that significantly improved corporate social responsibility (CSR) disclosure practices. The research stream was explored by a systematic literature review (Tranfield et al. 2003) and a bibliometric analysis (Zupic and Čater 2015). In particular, a specific focus is on the King III Report, as antecedent for refining the disclosure of CSR issues. In 1994, the first report (King I Report) was released by the “King Committee on Corporate Governance.” The main novelty resided in the relevance of both financial and nonfinancial views. In 2002, the first report was replaced with the King II Report. Specifically, the latter filled some earlier lacks, such as the need of adopting a robust risk management and reporting practices. In 2009, the King III Report defined the importance of financial and sustainability performance for stakeholders, in terms of assessing firm value. The King IV Report, published in 2016, is a further refinement of the South African reports, since the concept of “qualitative” corporate governance (CG) was integrated by including business ethics, good CG, and ethical culture.

An Overview of the King Reports

South Africa is not only at the forefront on CG issues but it is also the first country in the world to make Integrated Reporting (henceforth IR) mandatory (Ernst and Young 2012). As well known, IR represents “*a concise communication about how an organization’s strategy, governance, performance and prospects lead to the creation of value over the short, medium and long term*” (IIRC 2013). The aim of the IR is to provide benefits to a wider range of stakeholders through information enabling to consciously choose, in terms of financial capital allocation or investment decisions (IIRC 2013). In South Africa, CG was institutionalized thanks to the King I Report published by the “King Committee on Corporate Governance,” in November 1994 (IoDSA 1994). Eight years after, the King II Report (IoDSA 2002) enriched the CG measures and it included both CSR view and good CG (Painter-Morland 2006). This integration process was still ongoing. Indeed, the King III Report was released, in 2009 (IoDSA 2009). Seven years after (in 2016), the King IV Report was acknowledged (IoDSA 2016).

The King I Report was focused on several issues, such as the duties and the responsibilities of executive and nonexecutive board members, the stakeholder communication and the compliance with ethical standards (Rossouw 1997, 4 green). A lively debate on stakeholders took place (Freeman and Reed 1983). Indeed, this report overcame the entrenched view for which the board members were exclusively responsible to the shareholders, and it established that stakeholder communication is required (IoDSA 1994).

In the King II Report, the good CG is a relevant novelty (IoDSA 2002). Therefore, a broad section was devoted to the following seven characteristics of good CG: discipline, transparency, independence, accountability, responsibility, fairness, and social responsibility.

The King III Report was required to face up the changes in the international governance trends (IoDSA 2009). In the IR, firm should highlight the positive and negative effects on the economic and social fabric. In other words, it should exhibit

appropriate measures, in case of negative impact, and more broadly describe the possible actions for putting in place further improvements.

Still, the King IV Report stems from the three previous reports with the aim to refine some specific goals (IoDSA 2016). In particular, it encourages CG outcomes, such as ethical culture, good performance, effective control and legitimacy. The CG guidelines are adapted across a heterogeneity of industries and organizational types by promoting corporate disclosure policies for the benefit of stakeholders.

Such reports are crucial to reconvert the trends on CG toward responsible and sustainable social practices, in South Africa. Nonetheless, CSR is embedded in business awareness, and in the developed countries, it might be deemed a maturing trend, in the South African context (Kloppers 2018). Several studies emphasized the crucial role of CSR, in firm’s survival (Doni et al. 2021; Freeman et al. 2010; Ortiz-de-Mandojana and Bansal 2016). Sustainability reporting therefore represents a relevant opportunity, as CSR might contribute to foster firm’s reputation (Bebbington et al. 2008; Morales-Raya et al. 2019). In this sense, top management team is affected by stakeholder pressure, and it should be able to accommodate the demand of several stakeholder groups by deploying part of the resources to CSR (McWilliams and Siegel 2001). As a consequence of the conflicting interests, due to customers, employees, suppliers, community groups, governments, CSR domain is constantly developing. Therefore, updated sustainability reports are needed.

The King Reports: A Systematic Literature Review and Bibliometric Analysis

Research Methodology

The empirical analysis was conducted by a mixed approach based on a literature review and a bibliometric analysis. The purpose is to explore the current body of knowledge. First of all, it is conducive to specify that the King Report is the research stream mostly investigated by this

methodological approach, given that a scant and statistically nonsignificant literature emerges from the association of the following terms: “King Report” and “CSR” (Shuro and Stainbank 2014, 3 purple; Steyn and Niemann 2010, 5 green).

The VOSviewer software was used to carry out the bibliometric analysis (van Eck et al. 2006; van Eck and Waltman 2010), while the systematic literature review followed the approach suggested by Tranfield et al. (2003). Basically, the bibliometric analysis allows to depict the current extensions and developments in any research stream, by way of publication and citation records, alongside with topic clusters and theoretical frameworks. (Zupic and Čater 2015). The Scopus Database enabled to identify the more relevant papers. Once the dataset has been identified, the VOS analysis was performed. In particular, the aggregation criterion, named bibliographic coupling, and the co-occurrence matrix, were applied (van Eck et al. 2006; van Eck and Waltman 2010). The bibliographic coupling emerges when two documents, A and B, quote a third one, C (Zupic and Čater 2015). If two or more documents are bibliographically coupled, it is reasonable to assume they have a comparable approach when exploring a particular research question (van Eck and Waltman 2010; Zupic and Čater 2015). The co-occurrence matrix is a tool that adopts keywords to form a knowledge structure. The latter eases the identification of the main themes in a research field. In VOSviewer, the output is a two-dimensional map of keywords sparked from the presence and frequency of co-occurrences, which are related to their spatial proximity (van Eck and Waltman 2010).

Twenty-two out of the 33 papers, included in our refined dataset, were bibliographically coupled. As a result, 11 manuscripts were not coupled, in terms of shared references, and they were therefore excluded from the similarity analysis (Andersen and King 1987; Crafford et al. 2012; de Beer 2020; Koutoupis 2012; Macdonald et al. 2007; Magalhães and Al-Saad 2013; Mähönen 2020; Sarah 2017; Sigauke et al. 2015; Thakhathi et al. 2021; Tseane-Gumbi 2018). The VOSviewer routines were calibrated by using the association strength, in the normalization process.

The resolution value amounts to 1.50, while the minimum cluster size is equal to 3 manuscripts. With the aim to weight the items, the normalized citations were considered to render a fitting portrayal, even for the most recent papers (van Eck and Waltman 2010).

Lastly, drawing upon the foregoing results, a systematic literature review was accomplished (Tranfield et al. 2003). In essence, all the papers classified into each cluster were systematically analyzed by highlighting the main topics and outcomes to achieve an extensive understanding of this research field.

Results of the Bibliometric Activity Indicators

Figure 1 shows the distribution of the papers over time. In 2009, the academic interest started in this fascinating research domain. Indeed, such year corresponds with the publication of the King III Report (IoDSA 2009), when there was a high requirement for improving sustainability report, as a consequence of the changes, in the international governance trends. The number of the publications shows an increasing amount in 2020, due to the relevance of CSR practices, for both practitioner and academic audiences (Kraus et al. 2020; Rosati and Faria 2019; Xie et al. 2019).

Results of the VOS Analysis and the Systematic Literature Review

Building on the options provided by the VOSviewer software, the main results of the bibliometric analysis are summarized in Figs. 2 and 3. In detail, Fig. 2 highlights the most significant keywords.

On closer inspection, it is possible to plot the presence of five well-polarized clusters representing the research topics investigated with respect to the King Reports. Table 1 shows the descriptive statistics for each cluster. The red cluster, although collects more papers, records the lowest amount of citations. Vice versa, the blue, green and purple clusters fall in the first three ranks, in terms of citations. Four papers are the most positioned in such research field (Ntim et al. 2012a, b, 2013; Abeysekera 2013, green cluster). Overall, they gathered 530 citations.

King III Report and CSR, Fig. 1 Distribution of the papers over the years, 2009–2020

Figures 2 and 3 are strictly connected. The VOS keyword analysis (Fig. 2) displays the correlation between the arguments into each cluster, while the bibliographic coupling (Fig. 3) unveils the links among the papers mentioned in the reference lists. After having performed an in-depth examination of the earlier papers, first individually and then jointly, the research group identified specific subjects for every cluster, as detailed below.

Red Cluster: The Relevance of Stakeholder Engagement

In the red cluster, the stakeholder-inclusive approach represents the *fil rouge* across the four King Reports (Foster 2020; Natesan 2020; Ramalho 2020; van der Merwe 2020, red cluster).

Building on an in-depth analysis of the papers classified in this cluster, a stakeholder-inclusive approach is heavily recommended. Otherwise, a firm might have some difficulties in driving a long-term sustainable value creation (van der Merwe 2020). The King III Report thoroughly dealt with the concrete issues stemming from the relationships with stakeholders (Foster 2020).

The second theme pertains the main features suggested for the preparation of an appropriate sustainability report, such as the development of the social CG by considering a responsible

leadership and a specific core value system (Ramalho 2020). Accordingly, CG should recognize and radiate ethical values in the relationships with stakeholders (Judin 2020, red cluster).

Corporate culture is another topic to be mentioned (Kana 2020, red cluster). Indeed, the rigor and diligence akin to other strategic assets are highly needed, in order to stimulate human capital awareness toward good CG.

Green Cluster: The Magnitude of the Corporate Strategy

Corporate strategy and ethics of the governance (Rossouw 2020, green cluster) are the subjects ensuing from the examination of the manuscripts categorized, in the green cluster. Indeed, business strategy should target to integrate societal and stakeholder expectations into the sources of the competitive advantage (Steyn and Niemann 2010, green cluster). In this sense, the IR should exhibit firm's vision, stemming from the human capital values (Abeysekera 2013, green cluster; Doni et al. 2019). In this perspective, the handling of the relationships with the stakeholders is required. Along such a line of reasoning, it is relevant to mention the King III principles on stakeholder relationships, namely implementing a corporate strategy, giving suggestions to the top management and supervising crisis communication (Meintjes and Grobler 2014, green cluster).

King III Report and CSR, Fig. 2 Diagram of the VOS keyword analysis results on the King Reports

King III Report and CSR, Fig. 3 Diagram of the VOS bibliographic coupling analysis results on the King Reports

Furthermore, the effects on firm performance exerted by CG, that in turn is conditioned by ownership structure, were analyzed in this cluster (Mugobo et al. 2016, green cluster). Firms

compliant with the shareholding structure recommended by the King Report perform above average. Therefore, CG might be a relevant antecedent for enhancing firm performance.

King III Report and CSR, Table 1 Descriptive statistics of the clusters

Classification of the clusters	Number of papers	Total citations	Total normalized Citations	Tot. cit./Num. of papers
Red	6	9	37.00	1.50
Green	5	184	6	36.80
Blue	4	220	48.57	55.00
Yellow	4	76	18.47	19.00
Purple	3	176	15.01	58.67
Total	22	665		

With reference to the ethics of the governance, there is a clear consistency across the four King Reports (Rossouw 2020). The King I Report (1994) featured for a stakeholder-inclusive approach, for which the board of directors (BoDs) should work toward the accomplishment of firm's well-being (IoDSA 1994). Indeed, firm should disclose to its stakeholder employment, social responsibility and environmental issues. The King II Report (2002) stated that the BoDs should balance the mutual interests of shareholders and stakeholders (IoDSA 2002). Still, in line with the prior issues, the King III Report (2009) underlined the need to communicate the pivotal firm sustainability issues, in order to nurture a climate of trust with stakeholders (IoDSA 2009), and integrate sustainability and financial reports. At last, the King IV Report (2016) is now endorsed as the most suitable framework for interplaying with stakeholders (IoDSA 2016).

Yellow Cluster: The Stakeholder Pressure in the South African Context

Stakeholder pressure represents the first topic ensuing from the analysis of the papers contained in the yellow cluster (Jansen van Rensburg and Mmako 2017; West 2009, yellow cluster; Khale and Worku 2015). Indeed, the need for a huger transparent conduct, because of several corporate scandals, has placed a high pressure on the South African firms much to reform their reporting policies and develop an ethical philosophy of good governance (Albertus 2019, yellow cluster).

The second theme pertains the debate on shareholder versus stakeholder within the Anglo-American model, that is increasingly crucial for

some countries, such as South Africa (Andreasson 2011, yellow cluster; West 2009). Indeed, South African CG path developed on the grounds of the Anglo-American approach, though with some exceptions. Such approach emphasizes firm's responsibilities toward different stakeholders and promotes their engagement into business strategy. As a matter of fact, there has not been any considerable inclusion of stakeholder interests into CG structures, such as into board structure and financial reporting (West 2009).

Blue Cluster: The Disclosure of Good CG Practices

The topics, amenable to the papers comprised in the blue cluster, regard the main determinants influencing voluntary CG disclosure behavior (Ntim et al. 2012a, b, blue cluster) and CG characteristics (Ntim 2011; Waweru 2012, blue cluster).

The earlier studies argued that CG standards have commonly improved since the publication of the King I and II reports. In particular, the presence of a specific CG committee (i.e., the compliance and enforcement committee) positively affects voluntary disclosure (Ntim et al. 2012a). Still, the disclosure of good CG practices exerts a positive influence on firm value (Ntim et al. 2012b). In the same vein, the presence of independent nonexecutive directors positively conditions firm value creation (Ntim 2011; Waweru 2012). By contrast, other features of CG (i.e., the board size, the kind of the ownership structure) might lead in the opposite way, namely to a firm value destruction. These findings suggest to improve CG practices and minimize corporate failure, by safeguarding the interests of the minority shareholders, in South Africa (Waweru 2012).

Purple Cluster: The Social Responsibility Role Played by the Independent Auditors

Corporate disclosure (Coetzee and Erasmus 2020; Ntim et al. 2013, purple cluster) appears a dominant subject, probably because of the proximity to the blue cluster (Fig. 3). A prior study (Shuro and Stainbank 2014, purple cluster) argued that some kinds of business activities (i.e., the mining sector) disclose more information in the sustainability reports than manufacturing industry. One of the reasons might take root in a prominent support provided by the independent auditors, during and after the preparation of the foregoing report. Therefore, it is reasonable to contend that the sustainability reporting support strengthens firm propensity to engage in nonfinancial disclosure.

The corporate risk disclosure was another topic addressed in the manuscripts included in the purple cluster (Ntim et al. 2013). In detail, the board diversity and size as well as the independent non-executive directors positively affect the extent of corporate risk disclosure. According to the agency theory, the board diversity, in terms of ethnic and gender scopes, might enhance board independence and ameliorate managerial supervision (Cabedo and Tirado 2004; Elzahar and Hussainey 2012). Conversely, for instance, a lower degree of shareholder dispersion might have a negative influence over the extent of corporate risk disclosure.

A Focus on the King III Report as Driver of CSR Disclosure Policies

In March 2010, the Johannesburg Securities Exchange (JSE) established that the King III Report on CG principles falls within its listing requirements, and it therefore envisaged the compliance with IR (IIRC 2013). Thanks to the publication of the King I Report on CG (IoDSA 1994), the standards of conduct for BoDs of the listed companies, banks and state-owned firms have taken place. The main feature was the adoption of the stakeholder-inclusive approach. After 8 years, the founder of the King Reports, Prof. Mervyn E. King,

requested that the previous reports should be revised to include new sections on sustainability (IoDSA 2002).

The new Companies Act no. 71 of 2008 and the evolutions in the international governance trends stimulated the issue of the third report on CG. In 2009, the King III Report was released by the South African King Committee on CG, under the scientific coordination of the Prof. Mervyn E. King. Such report established the need of a holistic and an integrated depiction of firm's financial and sustainability performance (IoDSA 2009). In other words, firm should report on strategy, corporate governance path, and sustainability in an integrated manner, with the aim to fully describe their connectivity (Rensburg and Botha 2014; Corvino et al. 2020).

In the Commonwealth, 56 countries, including South Africa, adopted the “comply or explain” principle. There are several approaches of this principle, in particular, the King III report is on an “apply or explain” basis. Hence, the third report stated that *“it is the legal duty of directors to act in the best interests of the company. In following the ‘apply or explain’ approach, the board of directors, in its collective decision-making, could conclude that to follow a recommendation would not, in the particular circumstances, be in the best interests of the company”* (IoDSA 2009, p. 7). To this end, the BoDs might choose to apply the recommendation, in a different way, or apply an alternative practice, and, at the same time, target at the goals of CG principles concerning fairness, accountability, transparency and responsibility.

The purpose of the King III Report regards several governance issues, such as the responsibilities of the BoDs and the risk governance. The fundamental novelty resides in running corporate disclosure policies, in an integrated manner (Baboukardos and Rimmel 2016). Indeed, the King III Report recommended to prepare an IR rather than an annual and/or a separate sustainability statement (Wang et al. 2020).

In line with the prior research methodology, it is possible to identify the main keywords coming light from the literature review on the King III report (Fig. 4).

King III Report and CSR, Fig. 4 Diagram of the results deriving from VOS keyword analysis on the King III Report

In this research stream, Fig. 4 shows that CG and IR are fundamental subjects, by considering the Southern African context. The IIRC and the King III Report underlined the role of CG in attaining a high-quality sustainability reporting (Pavlopoulos et al. 2017; Wang et al. 2020). CG is therefore strictly related to the ethical leadership. Consistently with the King III Report, to get a flourishing democracy, the latter topic should be heavily deemed by the BoDs (Nevondwe et al. 2014). Lastly, the refinement of firm performance is probably due to a good CG. To this end, previous studies claimed that the underperformance might depend on the lack of adherence to the fundamental principles of good CG (Khale and Worku 2015).

In sum, during 20 years, from 1996 to 2016, the publication of the King Reports (from the first to the fourth version) spurred a continuous enrichment of CSR disclosure practices. First, in the South African and then in the global context, firms have been stimulated and/or induced to place more emphasis on the relevance regarding the core values system, the ethical culture, and a good CG.

Knowledge Management

Oluwasegun Seriki

Technological University Dublin, Dublin, Ireland

Definition

In understanding how to effectively manage knowledge, one needs to first recognize what constitutes “knowledge.” Blumentritt and Johnston (1999) explain that knowledge is sometimes used interchangeably with information, and in this case, the focus should be on information management as a proxy for knowledge management. However, several interpretations of what constitutes knowledge exist, suggesting that it is much more than information or data management (Carrillo et al. 2000). Grant (1996) also explained that knowledge must be transferable and have the capacity to be aggregated and appropriated.

One of the key concepts of knowledge was put forward by Nonaka and Takeuchi (1995), who defined knowledge as a dynamic human process of justifying personal belief toward the “truth” (i.e., a justified true belief). Later, Zack (1999) presented that for organizations to stay competitive, they must learn how to effectively and efficiently create, locate, capture, and share knowledge and expertise for problem-solving

and gaining advantage. Webb (1998) also defined knowledge management as the "...identification, optimisation and active management of intellectual assets to create value, increase productivity, and gain and sustain competitive advantage." Thus, the KM process involves the creation, dissemination, sharing, and storage of knowledge. Since the introduction of the European Union General Data Protection Regulation (GDPR) in 2018, a new aspect of knowledge management needs to be updated known as *data protection*.

Therefore, knowledge management can be defined as:

...the process through which knowledge is created, located, captured, shared, regularly updated, validated (-or fact-checked) and protected for creating efficiencies and gaining competitive advantage.

Introduction

Rennie (1999) outlined that knowledge is about knowing-why, knowing-how, and knowing- who and that it is a particular intangible economic resource from which future revenues can be derived. In understanding the concept of knowledge management, it is critical to examine what knowledge is, why it needs to be managed, how it can be managed, and who is responsible for its management. Von Kutzschenbach and Brønn (2010) postulated that the first phase in knowledge management is the acquisition of knowledge, with the later stages being the transfer, utilization, and storage of knowledge. Yang (2011) also asserted that KM is primarily concerned with identifying/creating, assimilating, and applying organizational knowledge to exploit new opportunities and enhance organizational performance.

Knowledge is considered a strategic asset to maintain competitiveness and create a niche for the firm within a sector of activity (Bergeron and Raymond 1992). It is not unusual to find firms lacking a structured approach to managing knowledge. How then do managers identify what knowledge to manage or exclude? How do they organize the firm structure to place responsibility on the individuals responsible for knowledge management for competitiveness? The purpose

of these questions is to understand what knowledge it is required for and what it contributes to, who needs it, how they will use it, and where they can find it when it is required (Carrillo et al. 2000).

Six critical considerations in the knowledge management process will now be explored in detail in this entry:

1. Know what
2. Know-why
3. Know who
4. Know-how
5. Know where
6. Know when

Know What (Identification)

The first step in knowledge management is "knowing what" kind of knowledge that the firm needs to acquire. Since knowledge has been formally recognized as a resource for attaining competitive advantage (Spender and Grant 1996), special attention needs to be paid to what type of knowledge a firm acquires for management. This process is known as knowledge identification. The identification of knowledge relevant to the achievement of organizational objectives is critical for knowledge management (Connaughton et al. 2015). When this identification process is complete, they can then be leveraged for competitiveness. Two broad types of knowledge are identified within KM literature – *tacit and explicit knowledge* (Bresnen et al. 2003).

Tacit knowledge is used in reference to knowledge gained via accumulated experience and learning of an individual (Debowski 2006), and it is usually developed via direct experience and action; is generally very logical and case-specific; is intuitively understood and applied; is challenging to articulate; and can only in most cases be frequently disseminated via interactive interaction and personalized experience (McAdam et al. 2007). Explicit knowledge, on the other hand, is usually transmittable in formal, systematic language and can be readily made available in a conceptualized format and stored in information systems (Takeuchi and Nonaka

2004). While explicit knowledge is easier to document and identify, tacit knowledge is linked to individuals engaged in *practices* and draws on the unconscious, intangible activities that have been gained over time and that are enacted collectively (Rasche and Chia 2009). In addition, tacit knowledge involves activities focus on the storage of knowledge in human minds and its subsequent sharing/transfer through direct social interactions, thus is often harder to manage due to its perceived stickiness and ambiguity in measurement.

The identification process for knowledge is the first, critical step in the management of knowledge, and Grant's (1996) knowledge-based view of the firm explains the crucial nature of knowledge for attaining long-term competitive advantage, mainly because its utilization can lead to value creation.

Know-Why

To promote knowledge capture and acquisition within knowledge management, individuals or firms need to know why a particular kind of knowledge needs to be acquired or captured (Chen and Hung 2010). Questions to be asked in this phase include the following:

- Of what operational or strategic importance is this knowledge?
- Is the knowledge critical to achieving the stated objectives of the firm? For instance, there is no point for a cloud software company to acquire logistics-related knowledge similar to fast-moving consumer goods (FCMG) firms.
- Why is this knowledge relevant?

The list of questions needed to be asked in the know-why phase is non-exhaustive but indicative of the typical issues that should arise in the knowledge management process. This will enable staff involved in the KM process to identify critical priorities and questions that should be asked concerning what the knowledge is required for and why it is being managed, thus providing clarity to those who will be involved in the management thereof.

Know Who

Within the KM process, managers must be able to identify with whom vital knowledge on projects are located and who has it (Yin 2003). It is also equally important to understand who will be utilizing knowledge and the key actors responsible for unlocking value from it. Under this heading, some of the questions to be asked include:

- Who has the knowledge (whether tacit or explicit), i.e., custodians of knowledge?
- Who will be using the knowledge, i.e., who needs to know what?
- Who is responsible for interpreting knowledge?
- Who is responsible for updating knowledge?
- Who authorizes access to knowledge?

The questions above will assist in identifying people-related aspects in the KM process, including critical actors in the network and whom to ask about specific problems and tasks.

Know-How (Procedures)

This step in the KM process includes identifying intra-firm organizational procedures/culture, much of which will be unwritten, informal, and tied into the culture of the organization. Prusak (1996) outlined that not only must a firm be conscious about what it knows but also how it uses knowledge is a critical determinant of its competitiveness. In the KM process, one must be able to clearly delineate the intra-firm procedures involved in knowledge management and the subsequent utility of the knowledge. This delineation will then guide how the firm will deploy organizational and technological resources and capabilities for explicating and leveraging the said knowledge (Hari et al. 2005). Also, this will assist in identifying the location of knowledge when it is needed.

Know Where (Location/Storage)

Within KM systems, users and managers alike must develop a capability that enhances all

employees to locate relevant knowledge/expertise quickly (Callahan 2002). Egbu et al. (2005) outlined that explicit knowledge is easy to be located but tacit knowledge is mainly in people's heads and therefore hard to organize into a system that can be searched. Kamara et al. (2003) also posit that locating knowledge repositories involves reliance on informal networks, as opposed to structured signposting to the required knowledge. KM processes should include structures that allow for accessible location of expertise, supported by either technology or easy-to-follow guidelines.

Know When (Timeline of Updating Knowledge and Timeliness)

When does knowledge become obsolete and required updating or outright discarding? These question needs to be incorporated into the KM process, to ensure that knowledge is regularly updated and those that are no more relevant are archived on demand. For instance, a company that used to have knowledge management systems for typewriting or sending faxes needs to consider archiving that knowledge and replacing them with modern typesetting using computers and email systems.

Offsey (1997) also espoused that timeliness is vital for KM systems, i.e., knowledge should be made available when(ever) it is needed. It is, therefore, critical for managers to know when a specific type of knowledge is required and the timing needed for making it available (Kim 2009). Due to the rate of changing dynamics in knowledge and depending on the industry, it is recommended that KM systems be updated within an agreed timeline.

Knowledge Protection

The introduction of the EU General Data Protection Regulation (GDPR) has necessitated the emphasis of a crucial component of knowledge management, known as knowledge protection. Allameh et al. (2011) outline that knowledge

protection involves activities for protecting knowledge against inappropriate use or being leaked inside or outside of the organization. Probst et al. (2000) also argue that knowledge must have limited access, especially that which is critical for competitiveness. Some of the restrictions that are used in practice include password technology, encryption, and more recently the use of blockchain technology.

Knowledge Validation (Fact-Checking)

How do we know that the knowledge held by an organization is valid or factual? Tchechmedjiev et al. (2019) outlined that knowledge management requires claims to be contextualized and labeled as accurate to facilitate supervision, validation, or reproducibility of such knowledge. Firms need to establish checking mechanisms to ensure knowledge is true and factual before it is replicated or shared. This component adds an additional step in the KM process, needed to ensure knowledge is accurate and true.

Summary

This entry has explored the concept of knowledge management, first outlining what constitutes "knowledge" and the process involved in its management. Six key components are described, with the additional, relatively underexplored area of fact-checking introduced. The definition presented in this entry covered vital areas such as the kind of knowledge involved, why and how it is managed, who is involved in the management process, where the knowledge is located, and when it needs to be updated. The definition also considers the protection of knowledge against inappropriate use or access.

International treaty under the UNFCCC

Definition

The Kyoto Protocol is an international agreement under the United Nations Framework Convention on Climate Change (UNFCCC) designed with the aim of reducing global greenhouse gas (GHG) emissions through binding commitments. The Kyoto Protocol was adopted in 1997, but it became enforceable in 2005. The Protocol is considered to be the first international step toward stabilizing global emissions of GHGs and the resultant climate change. Based on the principle of “common but differentiated responsibility and respective capabilities,” the Protocol assigned different binding targets for reducing the GHGs to the developed nations only (UNFCCC 2020a). Developing countries were asked to comply with the protocol voluntarily. The first commitment period for the Kyoto Protocol was from 2008 to 2012. “The target for the first commitment period was to reduce the combined emissions of GHGs by at least 5 percent below the 1990s levels” (United Nations 1998). In December 2012, the Doha Amendment to the Protocol was adopted with a second commitment period from 2013 to 2020. In order to further intensify the global efforts to deal with the threat of climate change, the Paris Agreement was reached in 2015.

Introduction

In the last few decades, growing scientific evidence and public awareness about the harmful impacts of escalating levels of GHG concentrations in the atmosphere on the ecosystem, climate change, and living organisms paved the way for concerted international efforts to deal with this situation. In 1992 at Rio Earth Summit, the UNFCCC agreed with the ultimate objective of “stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system” (United Nations 1992). The convention provided a framework for combined international efforts to deal with climate change issues by restricting average rise in global temperatures. The parties that ratified the convention

meet every year at the Conference of Parties (COP). In 1997, the third session of the COP was held at Kyoto, Japan, where the Kyoto Protocol was adopted. Under the Kyoto Protocol, binding targets were fixed for the participating industrialized nations to reduce GHG emissions. The Protocol became enforceable in 2005 when 132 countries signed the Protocol. Currently “There are 197 Parties to the Convention and 192 Parties to the Kyoto Protocol” (UNFCCC 2020b). Since 2005, a conference of parties serving as the meeting of the parties (CMP) is held annually along with the COP to check the implementation of the Protocol.

Commitment Period

The first commitment period for the Kyoto Protocol was from 2008 to 2012. In 2012, the Doha Amendment to the Protocol was adopted for a second commitment period starting from 2013 and ending in 2020.

Objective

The UNFCCC was adopted with the aim of stabilizing GHG concentrations in the atmosphere at such a level which would allow the ecosystems to adapt naturally to climate change and would ensure sustainable economic development of the countries (United Nations 1992). In order to achieve this objective, the convention made a broad framework with suggested principles, institutional arrangements, and required policy actions to be undertaken over a period of time. The Kyoto Protocol aims to achieve the broad objectives of the Convention through binding emission reduction commitments by the developed countries. The objective of the Protocol as mentioned in Article 3 was to reduce “the overall emissions of GHGs by at least 5 percent below 1990 levels in the commitment period 2008 to 2012” (United Nations 1998). The first commitment period covered six main GHGs which are specified under Annex A of the protocol. These gases are “Carbon Dioxide (CO₂); Methane (CH₄); Nitrous Oxide

(N₂O); Hydro fluorocarbons (HFCs); Perfluorocarbons (PFCs) and Sulphur Hexafluoride (SF₆)” (United Nations 1998).

Common But Differentiated Responsibilities

The Kyoto Protocol segregates participating countries into Annex I (Developed) countries and Non-Annex I (Developing) countries. It was acknowledged that owing to their industrial and development activities in the past, the developed countries were mainly responsible for the prevailing increased levels of GHGs in the atmosphere, and hence, they should primarily bear the burden of reducing GHG emissions. It was also recognized that various countries have different capabilities to deal with climate-related problems due to the difference in the level of their economic development. Hence, based on the principle of “common but differentiated responsibility and respective capabilities,” the protocol assigned different GHG reduction targets for the Annex I countries. The assigned amounts for Annex I countries are mentioned in Annex B of the Protocol. Article 3 of the Protocol specifies that the Annex I parties shall have joint as well as individual responsibility to ensure that their total emission of GHGs listed in Annex A is limited to their assigned amounts (United Nations 1998). Some developing countries signed the Protocol, but these were exempted from any binding commitments under the Protocol.

Compliance Mechanism

In order to ensure compliance under the Protocol and to hold parties accountable for non-compliance, the Kyoto Protocol provides for a comprehensive system of compliance. The compliance mechanism under the protocol has an effective monitoring, review, and verification system for facilitating and enforcing compliance with the commitments made under it (UNFCCC 2020a). The compliance committee has two branches: “a facilitative branch and an enforcement branch”

(UNFCCC 2008). The facilitative branch assists and guides Annex I parties in meeting their commitments. For this, it provides necessary technical, financial, and other assistance to the parties. The enforcement branch checks the compliance with the binding commitments and other requirements under the protocol and also determines the specific course of action to be undertaken for those who fail to meet their commitments.

Flexibility Mechanisms

Annex I countries are required to meet their targets mainly through the domestic actions within their national boundaries. In addition, in order to help developed countries to meet their reduction targets in a cost-effective manner, the Protocol provides for three market-based mechanisms. These are “Clean Development Mechanism (CDM), Joint Implementation (JI) and International Emission Trading (IET)” (UNFCCC 2010). The mechanisms are based on the principle that “it does not matter where emissions are reduced, as long as they are removed from the atmosphere” (UNFCCC eHandbook 2015). These mechanisms provide participating countries with lot of flexibility in the way they can meet their targets. Hence, these are also called flexibility mechanisms. The purpose is to help developed countries in meeting their emission reduction targets in a cost-effective manner and also to involve developing countries in the task of reducing global GHG emissions (UNFCCC 2010).

Clean Development Mechanism (CDM)

Under CDM, an Annex I party may start a GHG emission reduction or removal project (like reforestation or investment in clean technology or rural electrification by using solar panels) in a developing country. Usually the cost of establishing such projects in a developing country is relatively lower. The developed country gets the credit for emission reduction from these projects in the form of Certified Emission Reduction (CER) units. “Each unit is equal to 1 metric tonne of CO₂ equivalent and can be used by the developed

country for meeting its binding emission reduction targets” (UNFCCC 2010). The developing country where such projects are run gets the benefit of technology transfer and finance needed to implement such projects, besides getting the sustainable development advantage. This way, these countries can also contribute toward achievement of the ultimate goal of the UNFCCC.

Joint Implementation (JI)

Under JI, an Annex I country starts an emission reduction or removal project in another Annex I country to earn emission reduction units or carbon credits. These credits can be utilized for meeting binding targets of the country financing such projects.

International Emission Trading (IET)

The implementation of flexibility mechanisms led to creation of a new commodity in the form of emission reduction or removal units which is traded in the carbon markets (UNFCCC 2010). Under IET, countries with deficit of carbon credits can buy these in the carbon markets from parties having surplus of these credits. Trading is done in these markets through CERs and the process of buying and selling CERs is known as carbon trading. According to Article 17 of the Protocol, in order to supplement their national efforts to meet emission reduction commitments, the parties to Kyoto Protocol can also participate in emission trading to meet their targets given under Article 3 (United Nations 1998).

For participating in the flexibility mechanisms, the participating countries must meet the eligibility requirements specified under the Kyoto Protocol.

Amendments to Kyoto Protocol

Doha Amendment

In December 2012, Doha Amendment to Kyoto Protocol was agreed in the 18th Conference of Parties (COP 18) held at Doha, Qatar. The second commitment period was established from 2013 to 2020. The Doha Amendment included new commitments for the parties and revised the list of

GHGs. Nitrogen trifluoride (NF₃) was added to the earlier list of six GHGs (United Nations 2013). Several articles of the Kyoto Protocol were also updated in this amendment.

Paris Agreement

On 12 December, 2015, parties to the UNFCCC reached a landmark agreement known as the Paris Agreement at COP 21 in Paris. “The Agreement entered into force on 4 November 2016, thirty days after the date on which at least 55 Parties to the Convention accounting in total for at least an estimated 55 % of the total global greenhouse gas emissions have deposited their instruments of ratification, acceptance, approval or accession” (UNTC 2020). The central objective of the Paris Agreement is “to strengthen the global response to the threat of climate change by holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change” (United Nations 2015). In order to bring all the nations including developing countries together for making efforts to combat climate change, the agreement emphasized on the need for having an appropriate framework for transfer of technology, mobilization of financial resources, and capacity building (UNFCCC eHandbook 2015). All the parties are required to enhance their domestic efforts to achieve their binding commitments by preparing, communicating, and maintaining Nationally Determined Contributions (NDCs). The agreement requires regular reporting of the NDCs and the implementation efforts and provides for periodical “global Stocktake” to evaluate the collective progress toward achievement of the purpose of the agreement (United Nations 2015).

Summary

The UNFCCC (1992) provides the framework for combined international efforts to reduce the global emissions and to combat the climate change. At the third conference of parties to the

Convention in 1997, the Kyoto Protocol was adopted. The Kyoto Protocol is considered to be a milestone in the international climate policy. This is the first international step to reduce the global GHG emissions through binding emission limitation and reduction commitments for the developed countries. After end of its first commitment period (2008–2012), the Protocol was extended to 2020 during a conference at Doha, Qatar, in 2012. In 2015, the Paris Agreement was adopted at the 21st COP with the aim of bringing all the nations together for further strengthening the efforts to deal with the threat of climate change. The Paris Agreement came in force in 2016 for effectively replacing the Kyoto Protocol by 2020.

Labor Social Responsibility

María D. Odriozola, Elisa Baraibar-Diez and
Ignacio Llorente
University of Cantabria, Santander, Spain

Introduction

Since the 1950s, the inclusion of social responsibilities into companies, in addition to economic ones,

has been a constant concern, and in this sense, social pressures are increasing every time to satisfy the expectations that the different interest groups represent. Currently, United Nations (UN) is also a promoter of Corporate Social Responsibility (CSR hereafter) in all areas of society through Sustainable Development Goals (SDG). Both private companies and public institutions are working to improve their social, economic, and environmental indicators in order to contribute to the fulfilment of the SDGs for the year 2030.

However, the concept of CSR is broad, and due to the multiple dimensions that the concept encompasses, it is often not appropriate to use this extensive umbrella when dealing with actions aimed at specific interest groups or specific areas in business environment. The labor dimension plays a leading role within CSR, since it responds to the needs of the employees (primary stakeholders of the company), in addition to having the support of increasingly developed labor regulations that increase the need to legitimize the behavior of companies.

To refer to the labor dimension of CSR, the term “Labor Social Responsibility” (LSR from now on) is used. LSR “implies social responsibility practices developed by the company to improve working conditions.” Many times, companies are unaware of the huge number of labor practices that can be considered part of the company’s social responsibility, which slows its implementation. This contribution aims to clarify the role of labor practices in CSR as a whole,

improve the conceptualization and definition of the term LSR, identify the main areas of action to develop LSR, as well as standards for its disclosure. Finally, the work concludes describing some of the main outputs generated with a proper responsible labor management.

Labor Social Responsibility in the Multidimensional Construct of CSR

CSR is a multidimensional construct (Carroll 1979; Wood 1991; Schwartz and Carroll 2003). However, in the academic literature, we find discrepancies when determining the dimensions that compose it. There are authors classifying CSR actions according to the nature of the actions, social issues, or the attitude taken by the company in its development.

The classification of CSR actions in three concentric circles proposed by “The Committee for Economic Development” (CED) in 1971 was one of the first classifications for CSR practices. This classification defined an inner circle (with responsibilities inherent to economic activity, production of goods and services, employment, and economic growth), an intermediate circle (where awareness and sensitivity to social aspects take place, such as the environment, recruitment, and the relationship with employees), and an outer circle (social actions aimed at further improving the company’s social environment).

Sethi (1975) carried out an evolution of the three concentric circle classification, where he classifies the actions according to the degree of proactivity of the company’s actions. This classification distinguishes between denominating social obligation when the actions are in response to market forces or legal restrictions, social responsibility when they respond to prevailing social values, and social sensitivity when they are actions that anticipate social changes. Following this proposal, the classifications of Davis and Blomstrom (1975) and Wilson (1975) arose. All these classifications respond to the nature of the actions, whether they are economic or social and philanthropic, as well as the response capacity of the company in terms of proactivity.

However, these classifications did not show the main areas of action in which companies should work to be sustainable, so other classifications emerge to determine dimensions of CSR. One of the best-known models is the three-dimensional model of Carroll (1979), which uses three axes and classifies according to the response capacity of the company, the nature of the actions, and the social issues involved (Fig. 1).

Regarding the nature of CSR actions, Carroll (1991) also presents them in a pyramidal format, where he states that companies must achieve an economic objective, which is, work for profitability through the products or services offered. Subsequently, companies must respond to their legal obligations. The economic and legal nature of business actions makes them mandatory. Once the company has exceeded these previous thresholds, the ethical nature of the actions would be reached, where the companies respond to the needs of their stakeholders and thereby manage to legitimize their activity. Finally, at the top of the pyramid, philanthropic actions would be achieved when the company contributes and collaborates with the community to which it belongs. Subsequently, Schwartz and Carroll (2003) rethink the pyramid theory for being inaccurate and generating misunderstandings in the differentiation of ethical and philanthropic concepts, considering the latter as an expanded expression of ethical actions. Therefore, these authors establish three domains: economic, legal, and ethical.

Regarding the social issues involved in CSR, Carroll divides them according to the type of stakeholder to whom it concerns. That is why we find issues related to consumers, the environment, discrimination, product safety, workplace safety, and shareholders. This classification was not considered too clear either, and simplified classifications emerge, such as the one elaborated by the Green Paper of the Commission of the European Communities (CEC) (2001), where it is distinguished between the internal and external dimensions. The internal dimension responds to those aspects aimed at internal stakeholders over which the company has decision-making capacity and greater control, such as HR management, the use of resources, and their environmental impact. The

Labor Social Responsibility, Fig. 1 Three-dimensional model of CSR. (Source: Carroll (1979), p. 503)

external dimension responds to actions aimed at external stakeholders, and over which the company does not have absolute control, such as actions with the local community, partners, suppliers, or consumers.

These controversial models and the debates arising from them have given rise to simpler classifications such as that of Vilanova, Lozano and Arenas (2009), which distinguishes five dimensions: (1) the vision of CSR in the corporate sphere, (2) philanthropic relations with the community, (3) the workplace, (4) accountability and transparency, and (5) the commercial or business sphere.

It is necessary to bear in mind that the conceptualization of CSR has evolved over time, increasing social concerns. For example, the degree of environmental concern or equal opportunities in the labor market has increased considerably. That is why identifying and deepening in the dimensions of CSR, as well as the nature of the existing actions in each dimension, can favor the fulfilment of stakeholder expectations.

Specifically, in the workplace, actions aimed at improving the working conditions of employees could have a social or economic nature (since it also favors the results of companies) and legal or philanthropic (some will respond reactively to

labor legislation and others will be proactive actions voluntarily developed by the company). Regardless of the nature of the actions, knowing what type of actions each dimension involves is more useful to work on it. Authors such as Alvarado and Schlesinger (2008) consider it necessary to “deepen our understanding of the dimensions of CSR, as well as the possible influences on the image and reputation of the company.”

In this context, Labor Social Responsibility (LSR), which is the labor dimension of CSR, deserves to have prominence and be defined as labor practices that are identified in companies as those with the greatest impact on the organization; they are aimed at primary, internal stakeholders, with bargaining power and capable of legitimizing the company by generating reputation. Urcelay (2005) argue that “The first place where CSR manifests itself is in the policies that the company follows with its employees, who are the ones who make it possible for it to exist and to carry out its activity successfully.” Responsible management of a company’s employees not only has internal implications, as “human capital is one of the interest groups in which companies must support and promote their professional and personal development, since they are the basis of business growth and of the positioning in the

market; they are also the best publicists in the organization” (López et al. 2016).

Definition of Labor Social Responsibility

The labor dimension of CSR or LSR has been defined in the past as “those labour practices carried out voluntarily by the company in order to show its commitment to ethical behaviour in relations with its employees” (Odriozola et al. 2015). However, in recent years, growing labor regulations increasingly commit companies to improving working conditions. Regulatory changes in the business environment makes it necessary to rethink whether the LSR can be considered only when actions are implemented under the voluntary nature of the company, or if it can also be considered LSR in the face of a regulatory response.

Returning to the general construct of CSR (being LSR one of its dimensions), we find more recent definitions where business actions are taken into account in response to the needs of stakeholders, regardless of whether they are carried out voluntarily or in response to a normative text.

CSR was defined as “in addition to the strict compliance with current legal obligations, voluntary integration in its government and management, in its strategy, policies and procedures, of social, labour, environmental concerns and respect for human rights that arise from the transparent relationship and dialogue with its stakeholders, thus taking responsibility for the consequences and impacts derived from their actions” (Forum of experts on CSR 2007). It seems logical to think that, in many areas, voluntariness and legislative compliance can converge in the same action, and in fact, advances driven by public institutions together with the private initiative will lead to the achievement of more ambitious social objectives.

In the labor field, labor regulations have not ceased their growth and demand to guarantee the improvement of working conditions, as well as the information offered to the worker. For example, to favor to find the balance between work time

and personal time, the Directive (EU) 2019/1158 of the European Parliament and of the Council of June 20, 2019, on work–life balance for parents and carers and repealing Council Directive 2010/18/EU was implemented. To guarantee information on working conditions to the worker, the Directive (EU) 2019/1152 of the European Parliament and of the Council of June 20, 2019, on transparent and predictable working conditions in the European Union was approved. To guarantee equal treatment in employment and occupation, avoiding any type of discrimination, the Directive 2006/54/EC of the European Parliament and of the Council of July 5, 2006, on the implementation of the principle of equal opportunities and equal treatment of men and women in matters of employment and occupation was approved. All these regulations include aspects on which companies focus the LSR.

In addition, not only does labor market legislation exert an impulse for companies to be more responsible with their workers and therefore favor a better working environment, but also United Nations (UN) has committed 193 states to the sustainable development agenda “Transforming our World: the 2030 Agenda For Sustainable Development.” In this agenda and their sustainable development goals (SGD hereafter), there are objectives that are closely related to the LSR. In the human resources departments, there are actions aimed at improving the health and well-being of workers (SDG 3); actions to improve collaborations with training centers to favor the preparation of future employees, as well as continuous training of the workforce (SDG 4); actions to consider equal work in all areas of the company (hiring, promotion, conciliation, remuneration, communication, etc.) (SDG 5); and actions to ensure that working conditions are decent and favor growth (SDG 8).

Taking all the above into account, it seems necessary to consider that companies will carry out LSR when they respond to the needs of their employees and improve their working conditions, without differentiating whether the company is obliged to carry out the action or not, since many times the obligation will depend on the size of the company. For example, if a company allows a

flexible working day to its workers, they enjoy this possibility regardless of the cause that originates it. Therefore, the updated definition of the LSR concept would be:

Labour social responsibility (LSR) is the labour dimension of the CSR construct, which is made up of those labour practices carried out by companies with the aim of improving the working conditions of current employees, as well as to collaborate with public or private training institutions, NGOs or other labour intermediation organizations to favour the integration of future job seekers. These labour actions may be voluntary or may have been designed to respond to current labour legislation, although in any case, companies assume an ethical commitment in the management of their workforce.

Practices of Labor Social Responsibility

Going from the most general concept to the most concrete, known as funnel-shaped development, we have seen that LSR is a relevant dimension in the CSR construct, although, to promote the implementation of LSR practices, it is necessary to specify the different fields of action in human resource management.

Practices of labor social responsibility proposed in the green paper of the Commission of the European Communities (CEC 2001) would be classified as:

1. Lifelong learning.
2. Employee training.
3. Transparency about company information.
4. Balance between work time and personal life.
5. Diversity in the workforce.
6. Non-discrimination.
7. Equity in salary policy.
8. Profit sharing and ownership.
9. Concern about employability.
10. Job security.

Independent institutions develop standards for the publication of CSR information, such as the Global Reporting Initiative (GRI). GRI classifies the social information of the company in packages of measures or differentiated standards according to the subject discussed, which could be used to generate sustainability reports and that the

information is easily comparable between companies that follow its guidelines. The GRI 200 series deals with economic actions, the GRI 300 series deals with environmental actions, and finally the GRI 400 series deals with social aspects. Each of these standards includes specific measures for specific topics (Table 1). Within the GRI 400, great attention is devoted to the type of practices by which the company should report in relation to the working conditions of its employees:

In addition, the International Organization for Standardization (IOS) in its ISO26000 standard guide on social responsibility identifies the following categories in the workplace:

In the subject of "Employment and Labour Practices," ISO 26000 provides guidance on five issues:

1. Issue 1: Employment and employment relationships;
2. Issue 2: Conditions of work and social protection;
3. Issue 3: Social dialogue;
4. Issue 4: Health and safety at work;
5. Issue 5: Human development and training in the workplace.

Therefore, following the main guidelines or standards for the dissemination of LSR practices at the international level, there is a certain coincidence when describing the fundamental areas in which practices should be developed to improve the working conditions of employees (see Table 2).

Despite the fact that the classification of LSR practices can be different according to the standard consulted, we find the main common areas of interest in all of them:

- 1) **Transparency in Labor management:** It is essential to respond to the expectations of the stakeholders and that they can legitimize the activity of the company based on the fulfilment of their expectations, have quantitative and qualitative information on the HR management of the companies (hiring, turnover rates, leave or benefits for employees, work time management, etc.).

Labor Social Responsibility, Table 1 GRI indicators of labor practices and workplace ethics**GRI 401: EMPLOYMENT**

The reporting organization shall report the following information:

401-1	New employee hires and employee turnover	Total number and rate of new employee hires during the reporting period, by age group, gender and region. Total number and rate of employee turnover during the report period, by age group, gender and region.
401-2	Benefits provided to full-time employees that are not provided to temporary or part-time employees	Benefits, which are standard for full-time employees of the organization but are not provided to temporary or part-time employees, by significant locations of operation. These include, as a minimum: i. life insurance; ii. Health care; iii. Disability and invalidity coverage; iv. Parental leave; v. retirement provision; vi. Stock ownership; vii. Others. The definition used for “significant locations of operation.”
401-3	Parental leave	Total number of employees that were entitled to parental leave, by gender. Total number of employees that took parental leave, by gender. Total number of employees that returned to work in the reporting period after parental leave ended, by gender. Total number of employees that returned to work after parental leave ended that were still employed 12 months after their return to work, by gender. Return to work and retention rates of employees that took parental leave, by gender.

GRI 402: LABOR/MANAGEMENT RELATIONS

The reporting organization shall report the following information:

402-1	Minimum notice periods regarding operational changes	Minimum number of weeks’ notice typically provided to employees and their representatives prior to the implementation of significant operational changes that could substantially affect them. For organizations with collective bargaining agreements, report whether the notice period and provisions for consultation and negotiation are specified in collective agreements.
--------------	---	---

GRI 403: OCCUPATIONAL HEALTH AND SAFETY

The reporting organization shall report the following information for employees and for workers who are not employees but whose work and/or workplace is controlled by the organization:

403-1	Occupational health and safety management system	A statement of whether an occupational health and safety management system has been implemented, including whether: the system has been implemented because of legal requirements and, if so, a list of the requirements; the system has been implemented based on recognized risk management and/or management system standards/guidelines and, if so, a list of the standards/guidelines. A description of the scope of workers, activities, and workplaces covered by the occupational health and safety management system, and an explanation of whether and, if so, why any workers, activities, or workplaces are not covered.
403-2	Hazard identification, risk assessment, and incident investigation	A description of the processes used to identify work-related hazards and assess risks on a routine and non-routine basis, and to apply the hierarchy of controls in order to eliminate hazards and minimize risks, including: How the organization ensures the quality of these processes, including the competency of persons who carry them out; How the results of these processes are used to evaluate and continually improve the occupational health and safety management system. A description of the processes for workers to report work-related hazards and hazardous situations, and an explanation of how workers are protected against reprisals. A description of the policies and processes for workers to remove themselves from work situations that they believe could cause injury or ill health, and an explanation of how workers are protected against reprisals.

(continued)

Labor Social Responsibility, Table 1 (continued)

		A description of the processes used to investigate work-related incidents, including the processes to identify hazards and assess risks relating to the incidents, to determine corrective actions using the hierarchy of controls, and to determine improvements needed in the occupational health and safety management system.
403-3	Occupational health services	A description of the occupational health services' functions that contribute to the identification and elimination of hazards and minimization of risks, and an explanation of how the organization ensures the quality of these services and facilitates workers' access to them.
403-4	Worker participation, consultation, and communication on occupational health and safety	A description of the processes for worker participation and consultation in the development, implementation, and evaluation of the occupational health and safety management system, and for providing access to and communicating relevant information on occupational health and safety to workers. Where formal joint management-worker health and safety committees exist, a description of their responsibilities, meeting frequency, decision-making authority, and whether and, if so, why any workers are not represented by these committees.
403-5	Worker training on occupational health and safety	A description of any occupational health and safety training provided to workers, including generic training as well as training on specific work-related hazards, hazardous activities, or hazardous situations.
403-6	Promotion of worker health	An explanation of how the organization facilitates workers' access to non-occupational medical and healthcare services, and the scope of access provided. A description of any voluntary health promotion services and programs offered to workers to address major non-work-related health risks, including the specific health risks addressed, and how the organization facilitates workers' access to these services and programs.
403-7	Prevention and mitigation of occupational health and safety impacts Directly linked by business relationships	A description of the organization's approach to preventing or mitigating significant negative occupational health and safety impacts that are directly linked to its operations, products or services by its business relationships, and the related hazards and risks.
403-8	Workers covered by an occupational health and safety management System	If the organization has implemented an occupational health and safety management system based on legal requirements and/or recognized standards/guidelines: The number and percentage of all employees and workers who are not employees but whose work and/or workplace is controlled by the organization, who are covered by such a system; The number and percentage of all employees and workers who are not employees but whose work and/or workplace is controlled by the organization, who are covered by such a system that has been internally audited; The number and percentage of all employees and workers who are not employees but whose work and/or workplace is controlled by the organization, who are covered by such a system that has been audited or certified by an external party. Whether and, if so, why any workers have been excluded from this disclosure, including the types of worker excluded. Any contextual information necessary to understand how the data have been compiled, such as any standards, methodologies, and assumptions used.
403-9	Work-related injuries	For all employees: The number and rate of fatalities as a result of work-related injury; The number and rate of high-consequence work-related injuries (excluding fatalities);

(continued)

Labor Social Responsibility, Table 1 (continued)

		The number and rate of recordable work-related injuries; The main types of work-related injury; The number of hours worked. For all workers who are not employees but whose work and/or workplace is controlled by the organization: The number and rate of fatalities as a result of work-related injury; The number and rate of high-consequence work-related injuries (excluding fatalities); The number and rate of recordable work-related injuries; The main types of work-related injury; The number of hours worked. The work-related hazards that pose a risk of high-consequence injury, including: How these hazards have been determined; Which of these hazards have caused or contributed to high-consequence injuries during the reporting period; Actions taken or underway to eliminate these hazards and minimize risks using the hierarchy of controls. Any actions taken or underway to eliminate other work-related hazards and minimize risks using the hierarchy of controls. Whether the rates have been calculated based on 200,000 or 1,000,000 hours worked. Whether and, if so, why any workers have been excluded from this disclosure, including the types of worker excluded. Any contextual information necessary to understand how the data have been compiled, such as any standards, methodologies, and assumptions used.
430–10	Work-related ill health	The reporting organization shall report the following information: For all employees: The number of fatalities as a result of work-related ill health; The number of cases of recordable work-related ill health; The main types of work-related ill health. For all workers who are not employees but whose work and/or workplace is controlled by the organization: The number of fatalities as a result of work-related ill health; The number of cases of recordable work-related ill health; The main types of work-related ill health. The work-related hazards that pose a risk of ill health, including: How these hazards have been determined; Which of these hazards have caused or contributed to cases of ill health during the reporting period; Actions taken or underway to eliminate these hazards and minimize risks using the hierarchy of controls. Whether and, if so, why any workers have been excluded from this disclosure, including the types of worker excluded. Any contextual information necessary to understand how the data have been compiled, such as any standards, methodologies, and assumptions used.

GRI 404: TRAINING AND EDUCATION

The reporting organization shall report the following information:

404–1	Average hours of training per year per employee	Average hours of training that the organization's employees have undertaken during the reporting period, by: (i) gender; (ii) employee category.
404–2	Programs for upgrading employee skills and transition assistance programs	Type and scope of programs implemented and assistance provided to upgrade employee skills. Transition assistance programs provided to facilitate continued employability and the management of career endings resulting from retirement or termination of employment.

(continued)

Labor Social Responsibility, Table 1 (continued)

404-3	Percentage of employees receiving regular performance and career development reviews	Percentage of total employees by gender and by employee category who received a regular performance and career development review during the reporting period.
GRI 405: DIVERSITY AND EQUAL OPPORTUNITY		
405-1	Diversity of governance bodies and employees	Percentage of individuals within the organization's governance bodies in each of the following diversity categories: Gender; Age group: under 30 years old, 30-50 years old, over 50 years old; Other indicators of diversity where relevant (such as minority or vulnerable groups). Percentage of employees per employee category in each of the following diversity categories: Gender; Age group: under 30 years old, 30-50 years old, over 50 years old; Other indicators of diversity where relevant (such as minority or vulnerable groups).
405-2	Ratio of basic salary and remuneration of women to men	Ratio of the basic salary and remuneration of women to men for each employee category, by significant locations of operation. The definition used for "significant locations of operation."
GRI 406: NON-DISCRIMINATION		
The reporting organization shall report the following information:		
406-1	Incidents of discrimination and corrective actions taken	Total number of incidents of discrimination during the reporting period. Status of the incidents and actions taken with reference to the following: Incident reviewed by the organization; Remediation plans being implemented; Remediation plans that have been implemented, with results reviewed through routine internal management review processes; Incident no longer subject to action.
GRI 407: FREEDOM OF ASSOCIATION AND COLLECTIVE BARGAINING		
407-1	Operations and suppliers in which the right to freedom of association and collective bargaining may be at risk	Operations and suppliers in which workers' rights to exercise freedom of association or collective bargaining may be violated or at significant risk either in terms of: Type of operation (such as manufacturing plant) and supplier; Countries or geographic areas with operations and suppliers considered at risk. Measures taken by the organization in the reporting period intended to support rights to exercise freedom of association and collective bargaining.
GRI 408: CHILD LABOUR		
408-1	Operations and suppliers at significant risk for incidents of child labor	Operations and suppliers considered to have significant risk for incidents of: (i) child labor; (ii) young workers exposed to hazardous work. Operations and suppliers considered to have significant risk for incidents of child labor either in terms of: Type of operation (such as manufacturing plant) and supplier; Countries or geographic areas with operations and suppliers considered at risk. Measures taken by the organization in the reporting period intended to contribute to the effective abolition of child labor.
GRI 409: FORCED OR COMPULSORY LABOUR		
409-1	Operations and suppliers at significant risk for incidents of forced or compulsory labor	Operations and suppliers considered to have significant risk for incidents of forced or compulsory labor either in terms of: (i) type of operation (such as manufacturing plant) and supplier; (ii) Countries or geographic areas with operations and suppliers considered at risk. Measures taken by the organization in the reporting period intended to contribute to the elimination of all forms of forced or compulsory labor.

Labor Social Responsibility, Table 1 (continued)

GRI 410: SECURITY PRACTICES		
410-1	Security personnel trained in human rights policies or procedures	Percentage of security personnel who have received formal training in the organization's human rights policies or specific procedures and their application to security. Whether training requirements also apply to third-party organizations providing security personnel.

Source: Global reporting Initiative (GRI 400–410)

- 2) **Occupational Health and Safety:** Those LSR practices that respond to the purpose of ensuring the health of employees and preventing accidents.
- 3) **Training and Professional Development:** Those RSL practices aimed at increasing the human capital of the company, favoring that employees can respond adequately to the requirements of their current job and to future needs, in a way that increases their degree of employability and allow them professional growth.
- 4) **Diversity and Equal Opportunities:** This subcategory is crucial to guarantee a more open labor market that increases employment opportunities without any type of discrimination based on gender, race, religion or ethnicity. Diversity in the labor market should also favor the inclusion of people with disabilities.
- 5) **Participation and Association:** Those RSL practices that guarantee employee participation in the company are included, both in decision-making processes and in the distribution of benefits.

Outputs of Labor Social Responsibility

There is a widely studied paradigm in the academic literature, which analyses the relationship between Corporate Social Performance (CSP) and Corporate Financial Performance (CFP). Corporate social performance can be measured through the CSR actions carried out by the company or through its reputation. In the aforementioned paradigm, the impact of different CSP measurement

variables on economic performance have been studied through indicators of economic or financial profitability. Regarding these relationships, a majority of studies justifies a relationship of positive impact between social actions and financial performance in the company (Orlitzky et al. 2003). Although, there are also studies that conclude the existence of an inconclusive, neutral, or negative relationship.

In the specific case of LSR's actions, there are evidence that shows that the actions developed to improve the company's work environment improve its image. The image is an external assessment of the company based on the information available. However, reputation is another measurement that also includes the internal assessment of the company's stakeholders.

In the workplace, job reputation is "the result of the perceptions of the company's stakeholders on past actions and the reflection of their future perspectives on the company's job quality in relation to competitors and job providers" (Odriozola et al. 2015). Obviously, to generate this asset is necessary that companies communicate labor practices appropriately. In this sense, many companies publish information on LSR through their annual CSR reports, following standards such as the GRI. Additionally, it is also possible to find information disclosed directly by employees with storytelling techniques, sharing experiences, short corporate messages or specific LSR practices. This communication of labor practices has a double purpose; first favoring employee engagement, and second, increasing the credibility of the message, since the messages provided by employees are seen by external agents with the highest degree of trust.

Labor Social Responsibility, Table 2 Comparison of the subcategories of labor practices according to the main CSR disclosure guidelines

Green paper – CEC	GRI 400–410	ISO 26000

Profit sharing and ownership	GRI 408: Child labor	
Concern about employability	GRI 409: Forced or compulsory labor	
Job security	GRI 410: Security practices	

The labor information disclosed through various methods and channels about the company and the actions directed at employees builds a labor reputation that will provide competitive advantages to the company. The consolidation of the labor reputation in a sustainable way allows companies to generate an intangible, non-marketable asset of great value for it. For the labor dimension, we can find multiple rankings of labor reputation that identify the best companies to work for, sometimes for specific groups and others in a generalist way. The appearance in these rankings facilitates the attraction of talent as well as favors the retention of the talent hired. Some examples of these labor reputation rankings can be: “Working Mother,” “Great Place to Work,” “100 Best Companies to work for.” Finally, previous studies of the literature show that a higher labor reputation has a positive and significant impact on corporate financial performance (CFP) (Chauvin and Guthrie 1994; Hannon and Milkovich 1996; Lau and May 1998; Filbeck and Preece 2003; Fulmer et al. 2003; Odriozola et al. 2018).

Key Issues and Future Directions

- LSR disclosure

Description

Modern industrialization has been both the pinnacle of human innovation and the catalyst for our planet's deterioration. Because of this, leaders of organizations representing all sectors, sizes, markets, and influence are recognizing their organization's impact on our natural environment. They are refocusing their organizations' efforts on eco-efficiency and eco-friendly practices like renewable energy, sustainably-sourced materials, and carbon neutrality. But what does leadership for organizational sustainability look like? This essay defines leadership communication within the context of organizational sustainability initiatives, discusses transformational leadership and instrumental leadership communication behaviors, and considers cultural differences in follower expectations for leaders' management and communication behaviors. A communication-focused theory, the coordinated management of meaning approach, is discussed as an effective approach for leaders to use to create and instill meaning in their followers. Finally, the focus shifts to discussing how leaders can use communication strategically to promote support for their sustainability-related initiatives.

Defining Leadership

In order to understand leadership communication and its relationship with sustainability, it is important to first define leadership. The term "leadership" is associated with multiple words and

characteristics – management, charisma, innovation, creativity, and transformation, among others. People have struggled to reach just one definition of leadership. Some suggest it is the process of one individual influencing others to reach a common goal, many describe it as creating positive change for the common good, and others conclude it is simply making things better. For this essay, John Kotter's (1990) definition is most appropriate. Kotter defined it as "the fundamental purpose of leadership is to produce useful change, especially non-incremental change" (as cited in Summerfield 2014). Organizational changes related to sustainability often involve organizational goals, culture, processes, staffing, and relations with key external groups. Leaders must prepare their followers for and navigate them through such changes.

Leadership is not always discussed in terms of one person who directs a group of people. Sometimes leadership is discussed in relationship to an organization or group of organizations that create and innovate more effective, efficient, and economical practices of doing business. In this essay, however, we focus on leadership as the behavior of an individual (e.g., CEO). In governmental, nonprofit, and for-profit organizations, successful leadership is often associated with increasing an organization's success and creating positive change, but it also involves guiding an organization through challenges and crises. In this essay we focus on the communication a leader uses to encourage his or her employees to help their organization become more sustainable. Sustainable organizations seek to reduce their use of natural resources and minimize pollution and treat employees, community members, and society fairly, all while reaching the other organizational goals (e.g., maximizing growth, creating more resilient communities).

Leadership Theories

Early leadership efforts sought to identify the key traits that make someone a leader (e.g., outgoing, determined). But then the focus shifted to

transactional and transformational leadership styles (Bass 1985). Leaders often focus on five priorities: "using strategic vision to motivate and inspire, empowering employees at all levels, accumulating and sharing internal knowledge, gathering and integrating external information, and challenging the status quo and enabling creativity" (Dess and Picken 2000, p. 19). These priorities overlap with the idea of transformational leadership. Today, many people look at how leaders use communication to create a shared vision for their employees (e.g., the coordinated management of meaning approach). We begin by focusing on transactional and transformational leadership.

Positive organizational changes generally are influenced by the actions of transformational leaders as opposed to transactional leaders. Transactional leadership is rewards-based. Followers are motivated by their relationship of exchange with the leader to produce results. When an employee produces desirable work, his or her behavior is rewarded by the transactional leader. Transformational leadership centers on a leader's ability to articulate his or her vision of success and create a vision of the future for followers while recognizing what makes each follower unique. Such leaders create a sense of shared purpose among their followers. Although transformational leadership is often identified as more effective than transactional leadership during times of organizational change, both are important.

Bass (1985) described four behaviors of transformational leaders: idealized influence, inspirational motivation, intellectual stimulation, and individual consideration. Idealized influence evokes loyalty from followers because the leader has high moral and ethical standards and is held in high regard by his or her subordinates. A leader who embodies inspirational motivation has a clear and strong vision for the future that fosters enthusiasm and confidence within followers. Intellectual stimulation is brought on by a leader who encourages divergent thinking that challenges organizational norms, ultimately enabling followers to develop innovative strategies for

problem-solving and creative solutions. Lastly, a leader's individual consideration acknowledges that each follower is a unique individual and that these unique differences need to be nurtured differently to produce desired outcomes. All four of these behaviors involve a leader's strategic and skillful use of communication. In reviewing many studies of transformational and transactional leadership, Bono and Judge (2004) found that personality (e.g., outgoing, calm) has little to do with successful transformational leadership behaviors in comparison to communication abilities. Leaders who want to help their organizations become more sustainable can learn to become transformational leaders.

But leadership involves more than idealized influence, inspirational motivation, intellectual stimulation, and individual consideration. Leaders must critically analyze external environments for opportunities and threats as well as identify and articulate goals and strategies to help their organizations become more sustainable. Instrumental leadership involves a leader's ability to influence adaptation to external environments while simultaneously motivating followers through vision-casting and mission-sharing during their organization's transformational process. Antonakis and House (2014) identify four aspects of instrumental leadership that are grouped under two headings, *strategic leadership* and *follower work facilitation*. In terms of *strategic leadership*, two abilities are key: environmental monitoring and strategy formulation and implementation. Environmental monitoring involves understanding an organization's strengths and weaknesses and then paying attention to information existing outside the organization (e.g., in the broader business environment, in terms of technological changes) in order to identify potential opportunities or threats. Strategy formulation and implementation involves those actions (e.g., the creation of objectives, goals, and policies) leaders take to support their organization's strategic vision and mission which the leader has a hand in crafting. The second heading, *follower work facilitation*, involves path-goal facilitation and outcome monitoring. Path-goal facilitation "addresses leader behaviors

targeted towards giving direction, support, and resources, removing obstacles for goal attainment and providing path-goal clarification" (Antonakis and House 2014, p. 750). Outcome monitoring "entails a leader's performance-enhancing feedback useful for goal attainment" (Antonakis and House 2014, p. 750). Having the capability to communicate the analysis and implementation of *strategic leadership* and *follower work facilitation*, the authors argue, is what creates an instrumental leader. This type of leadership can be even more effective than transformational leadership. An instrumental leader displays all the communication-focused aspects of a transformational leader with an added hyper-awareness to external environments that may have a significant impact on their organization and the people who comprise it. Increasing environmental threats, dwindling natural resources, changes in market preferences, technological and legal changes, and competitor pressures are among the sustainability-related changes such leaders must take into consideration.

Cultures and Leadership Norms

Globally, organizations are enacting creative new initiatives related to environmental and social sustainability. Therefore, leaders who plan to work in a country outside their own or researchers investigating leadership and sustainability topics outside their home countries need to be aware of cross-cultural differences in leadership behaviors and follower expectations. Two streams of cross-cultural leadership research exist (Arvey et al. 2015). Some people believe that many leader behaviors are universally accepted and effective because leaders face common problems that involve how to organize, motivate, and influence others to accomplish organizational goals. Some universally-endorsed leadership qualities include being trustworthy, just, and honest; having foresight and planning ahead; being positive, dynamic, encouraging, motivating, and building confidence; and being communicative, informed, a coordinator, and a team integrator (House et al. 2004).

The second stream argues that cultural forces affect which leader behaviors are usually accepted, enacted, and effective within a setting. The GLOBE (Global Leadership and Organizational Behavior Effectiveness) project provided the first large-scale empirical evidence that societies' cultural values influence leadership behaviors and follower expectations. The GLOBE research team surveyed more than 17,300 middle managers from 951 organizations across 62 business-oriented societies (House et al. 2004). They found a specific set of criteria followers use to evaluate their leaders which are called culturally endorsed implicit leadership theories (CELT) (Arvey et al. 2015). Even though transformative leadership appears generally valued, significant variability exists among countries. Generally, the greater overlap between a CEO's leadership behavior and a society's CELT, the more acceptable the behavior and the higher a firm's performance. Scholars investigating CELT behavioral expectations have generally not focused specifically on preferred leadership communication behaviors. However, to learn more about leadership communication similarities and differences in the GLOBE countries, see the work of Cherfan (2016).

Communication and Leadership

In our discussion of transformational and instrumental leadership theories, communication was mentioned, but it was not the focus of either theory. To take a communication approach to understanding leadership, communication must take center stage. "Communication not only constitutes one of the crucial aspects of leadership performance, but leadership can productively be viewed as a communication process" (Schyns et al. 2008, p. 1). In organizations undergoing transformational changes related to sustainability, transparent and empowering leadership communication is key. Transparency comes into play when a leader is honest about the current state of the organization, shares his or her vision for the future, and describes what is expected from followers. Transparent

communication helps build a clear and mutual understanding of an organization's mission and goals and describes the progress being made toward reaching those goals. It requires face-to-face dialogue with followers as well as addressing them as a whole group to create a shared sense of meaning.

Communication takes center stage with the coordinated management of meaning (CMM) perspective of leadership (Smircich and Morgan 1982). The CMM perspective suggests that people within a given communication context (e.g., a meeting to create or discuss proposed sustainability initiatives) simultaneously construct social realities for themselves. This is particularly helpful when exploring leadership because it views the basic nature of leadership as a phenomenon involving social processes. Leadership results from a social process of interactions that co-creates meaning which is shaped by the leader and interpreted by the follower. Leaders strategically use communication to frame and define reality for their followers. As leaders manage meaning, they highlight particular aspects of the overall flow of experience occurring in a particular context. That is, they pinpoint the parts of the ongoing and changing reality they want their followers to pay attention to and recommend actions to take in response. Those being led see the action being promoted as a sensible and viable action. Leaders make actions personally meaningful to those who must implement them. Successful leadership allows organizational members to positively internalize the same actions, rules and guidelines, and purpose and meanings. Together, leaders and followers discuss implementation choices, possible futures, and next steps.

Leadership, Communication, and Sustainability

Given the increasing severity of environmental threats, dwindling natural resources, and market, legal, and political changes, it is necessary that organizations reflect on their environmental impact. Leaders can use effective communication

strategies and framing to enact their vision and mission to enhance sustainability within their organizations. By becoming transformational or instrumental leaders, they can enable and empower followers to press forward toward creating more sustainable organizations. Such leaders can use communication to create an inspirational and energizing vision, demonstrate confidence in themselves and their mission, set challenging goals, and enlist others to support their vision and mission. They can stir emotions (e.g., trust, loyalty), evoke symbolic images and expectations, create a shared sense of identity, inspire desires, develop fresh approaches to long-standing problems, seek out risks where opportunities and rewards appear likely, and encourage followers to generate new options (Allen 2016).

One interesting model links environmentally-specific transformational leadership and leaders' workplace pro-environmental behaviors to employees' proenvironmental passion and behavior (see Robertson and Barling, 2013). Environmentally-specific transformational leadership involves leadership behaviors focused on encouraging pro-environmental initiatives like saving environmental resources and finding new ways to do business that are better for employees, communities, and the natural environment. When leaders display environmentally-specific transformational leadership behaviors, their employees are influenced to become more interested in and passionate about the environment which leads to more pro-environmental employee behaviors. To positively influence their employees' pro-environmental passion and behaviors, leaders should share their own environmental values, encourage employees to achieve at an aspirational level, help employees think about issues in new and innovative ways, and create a personal relationship with employees. Many leaders are already taking such actions, and researchers are investigating what they are doing. If you want to read some examples of leaders who are strategically using communication to create more sustainable organizations, see Allen (2016).

Conclusion

In this essay we define leadership within the context of organizational sustainability initiatives, discussed transformational leadership and instrumental leadership behaviors, examined cultural differences in follower expectations for leaders' behaviors, and focused on a key communication theory of leadership, CMM. By applying the concepts discussed in this essay, a leader can become more effective in their ability to inspire and guide followers toward a shared vision for the future of their organization, industry, and planet.

Further research should investigate culturally-endorsed leadership theories generally and communication expectations specifically as they relate to sustainability-related initiatives. Additionally, researchers should investigate the role of leadership communication at the interorganizational level in terms of innovation and sustainability initiatives involving information-sharing and collaboration. Finally, future research should examine how organizations use communication strategically to lead other organizations and their industries to become more sustainable.

Definition

Lean Thinking is a managerial philosophy originally born on the shop floor of the Japanese automotive firm Toyota and gradually propagated all over the world. The Toyota Production System (TPS) is a system which enables a company to face its competition by focusing on providing its market with a better answer, increasing efficiency and Total Quality. The TPS moves production from a push approach to a pull approach, where the market drives the production flow and not vice versa. Consequently, inventory has to be reduced and all waste has to be eliminated. The principles and the tools of this system helped Toyota to be successful in its sector and led Western firms to study and imitate the approach. The model of Lean production rapidly evolved within Lean Thinking as a more comprehensive philosophy, going beyond the production area and being applicable to all organizational functions (Lean organization) and emphasizing the human factors. At the same time, Lean Thinking forced organizations to scrutinize their boundaries and to involve other actors, especially in supply chain management. More recently, the relationship between Lean Thinking and Sustainability appears to be a promising integration of Lean tools and Sustainability tools with the aim of developing new models.

Introduction

The search for efficiency has always challenged organizations. In the Japanese context, this issue

became more critical after the Second World War, when the country underwent a process of reconstruction and faced global competition. The automotive sector was primarily interested in entering the global market but had some weaknesses when competing with firms that had a consolidated position in the market. Therefore, the Japanese industry overhauled the production system from a push approach (typical in occidental mass production) to a pull approach, driven by customer demand. In addition, the system refers to different principles and uses many new tools in supporting the approach. As this new method of producing goods was born in Toyota, this new system was named the Toyota Production System (TPS) and evolved over the following decades. The unexpected success of the Japanese automotive sector forced firms all over the world to understand the system and its roots and to try to apply it in other sectors and geographical contexts. The TPS evolved to Lean Thinking and, in recent years, intersected the issue of Sustainability.

In its attempt to describe the evolution of TPS and point out relevant issues, this chapter is articulated as follows: first, it briefly describes the origin and evolution from TPS to Lean and Green Thinking. Second, it focuses on the central question of “waste” in Lean production; then it summarizes the principles and tool of Lean Thinking. Finally, it focuses on the interrelationships between Lean Thinking and Sustainability.

A Brief History

Even though production efficiency has been centralized since the beginning of the twentieth century, and even though it could be referred to in Ford’s methods of standardization, it became crucial when the Japanese automotive industry opened to global competition after Second World War, and especially in the 1970s. Toyota, taking into consideration the contribution of managerial systems established in the United States, built an original production system, called TPS. The TPS was described by Ohno (1988), who indicated that the origin of TPS was in the Jidoka, a tool implemented at the beginning of the twentieth

century by Toyota’s founder, Sakichi Toyoda. In particular, Jidoka, or autonomation, is a system that allows the company to detect problems and automatically stop production. The system evolves through its so-called “automation with human touch”, as the workforce has a fundamental role in analyzing and solving the problems that halt the process. The founder’s son introduced the relevance of acquiring raw materials and product at the same time and in the required quantities; this was the basis of just in time (JIT).

Starting from these roots, the TPS improves the system by considering the market as the driver of production, moving from a push system (mass production), based on forecasted demand and the production of the predicted quantity needed, to a pull system. In this system, the production is “pulled” by the customers, and the firm arranges its processes and the rhythm of production to the takt time (calculated by dividing the available production by the number of items to be produced).

The system challenges the organization to improve its efficiency by eliminating unproductive time and waste.

The Toyota system is globally recognized, thanks to Womack et al. (1990) in their book entitled *The Machine That Changed the World*. In this work, the authors report the result of 5 years of research within the Massachusetts Institute of Technology (MIT) regarding how the automotive sectors around the world faced the oil crisis in the 1970s: the research underlines how the TPS, named “Lean production” in the book, has been the driver of the enormous global success of the Japanese automotive industry.

After the publication of the book, many organizations considered adopting Lean production. Initially, implementation methods concerned the automotive industry, where the TPS was born, but the potential of the methodology gradually emerged in two directions. First, the approach could be expanded out of the shop floor and extended to other firm areas (i.e., product development) and lead to “Lean organization.” Second, Lean organization is not limited to the original automotive sector but could be successfully applied in other sectors.

This evolution was captured and described by Womack and Jones (1996) in their book *Lean Thinking. Banish Waste and Create Wealth in Your Corporation*, with the intent to generalize the basic concepts in order to apply them to any company in any industry.

Over the following years, many authors studied the topic of Lean Thinking, investigating cases of implementation in many areas (i.e., marketing and sales, accounting, etc.) and different sectors, especially in the services industry. Meanwhile, a number of authors discussed the difficulties in adapting the Japanese culture and the model to the occidental context and the impact on their human resources and the organization as a whole.

One of the emerging issues has been the increasing relationship between organizations in the supply chain. This is partially a consequence of the fact that if a firm is “Lean,” it needs to have strong collaborations with suppliers to keep processes fluid and to receive materials at the right time and in the right quantity. Similarly, a Lean organization has to be connected with customers and the market in order to implement the pull system. In other words, it could be difficult for an organization to be Lean without having partners who have adopted the same approach.

In more recent years, the growing concern about the environment and Sustainability challenges has led every organization to evaluate its impact on global Sustainability and to find the best way to conciliate organizational goals with the organization’s responsibility for future generations. The ongoing debate focuses on the

ability of Lean Thinking to support the path to Sustainability and on how the Lean Thinking and Green Thinking concepts and tools could be integrated. Milestones in Lean Thinking’s history are summarized in Fig. 1.

Lean Production and Waste

In the first interpretation, the meaning of Lean production was associated with “doing more with less,” emphasizing the goal of eliminating waste and improving productivity. Another characterization of Lean Thinking since its origins has been the orientation to both the customer and the market as drivers of production. The goals of Lean production can be summarized as (1) rapidly satisfying market demand, (2) minimizing inventory, and (3) reducing waste. Although these points are cornerstones of the methodology, Lean Thinking is a wider approach and involves the entirety of the organization.

In particular, waste (*muda* in Japanese) is considered to be a critical factor when pursuing Lean Thinking goals. The Lean Thinking methodology notes seven potential areas for waste (Fig. 2):

- **Transportation:** raw materials and products must be moved from one physical area to another. This activity does not directly add value to the product but is necessary in every production process. When materials and products are transported and handled too many times, the risk of damage and the loss of time through delays may arise.

Lean Thinking,

Fig. 1 From Jidoka to “Lean and Green”

Lean Thinking,**Fig. 2** The seven wastes (muda) in Lean production

- **Waiting:** in every process, an operator can perform their job when other activities are complete. If the work cannot start, as the operator is waiting for the conclusion of other phases of the process, their time is wasted, and this will influence the following activities. This waste could have several reasons, i.e., lack of materials, delays in the previous activities, bottlenecks in the process, etc.
- **Motion:** people move materials from one point to another within a workstation. TPS creates a layout that is ergonomic and allows the avoidance of unnecessary movement, walking, and lifting and so reduces the loss of time and the risk of stress. Jobs with excessive motion have to be redesigned to make the work more fluid.
- **Inventory:** materials, works in progress, and finished products cause the presence of inventory in an organization. Usually, inventory is a means through which to manage the variability of the procurement markets, production process, and customer demand. Inventory in this sense acts as a buffer to balance the production process. However, inventory is a cost in terms of the value of the goods, the space absorbed, and the eventual obsolescence or deterioration of the working capital. Lean Thinking suggests reducing the inventory as much as possible and, through JIT, to aspire to obtain “zero inventory.”
- **Inappropriate processing:** this waste is often described as “using a sledgehammer to crack a nut.” The utilization of equipment too sophisticated in relation to their use is a waste of resources and causes unnecessary costs. Lean Thinking encourages orienteering the company to a lower level of automation and to choose equipment that is flexible enough to permit the beneficial combination of production steps.
- **Overproduction:** often firms produce a quantity of product higher than the actual market demand by attempting to meet unexpected opportunities and to exploit their production capacity. According to Lean Thinking, this approach generates waste and causes inefficiency in the system. In this sense, JIT contributes to reducing over-processing and inventory. An important action is to improve the versatility of machines and equipment and involving the workers to facilitate changing from one production phase to another.
- **Defects:** if the product does not adhere to the attributes and quality requested by the client, the organization fails in pursuing its primary goal: to be customer-oriented. Moreover, defects cause rework and new checks and inspections; moreover, they have a direct impact on the flow of the process, with interruptions, extended lead time, and problems for other products.

As a consequence of the extension of the Lean approach out of the shop floor, practitioners have considered more potential waste, such as inappropriate use of spaces, waste in communication and in the information flow, and the bad use of human resources and competencies.

The Principles and Tools of Lean Thinking

Lean Thinking is a broad approach and, as described by Womack and Jones (1996), rests on five principles (Fig. 3):

1. Identify the value
2. Map the value stream
3. Establish flow
4. Create pull
5. Seek perfection

Identify the Value

The concept of value could be associated with different meanings. Lean Thinking considers every organization as a group of different activities that generates processes, thus producing value. This is partly coherent with the concept of

a value chain, as introduced by Porter in 1985, as a fundamental analysis for creating competitive advantages. As enterprises are customer-oriented, the value has to be created for customers.

In general, an activity (or process) creates value if the customers detect the activity, appreciate it, and assign a value to it (e.g., in terms of price paid). This definition contributes to pointing out that there are usually three types of activities present in an organization: (i) activities that create value, (ii) activities that do not directly create value for the customer, and (iii) activities that do not create value and must be eliminated.

Activities that create value (i) have the three characteristics described above and are fundamental for the organization.

The second type of activities are not perceived as creating value for the customer but are necessary for the firm. For example, the activity of producing reports for the regulator of the sector (i.e., bank) is essential for the organization and probably for the stability of the markets but is not considered to be valuable by the customer, who often fails to notice this activity at all. Most support activities are part of this group of activities.

The third type of activities, those that don't create value either directly or indirectly for the customer, are worthless and have to be eliminated because they absorb resources without proving themselves to be useful for the customer.

Map the Value Stream

A Lean production system considers a single product or a family of products with similar characteristics and analyzes its value stream. It is composed by two flows: the physical flow that moves from the raw materials to the finished product and the information flow that moves backwards from the customer's order and pulls the production. The organization must correctly synchronize the flows. In Lean Thinking, the value stream doesn't take into consideration the production alone but also other areas that contribute to creating value for the customer. This is then extended to product development, marketing and administration, etc.

The map of the value stream considers the flows of value in every stream for every product

Lean Thinking, Fig. 3 Principles of Lean Thinking

(or family of products) and, through a visualization, produces relevant information. First, it evidences the different activities and their position in the value stream. Second, it makes clearer where waste is located and its causes. It supports the management in finding the activities that don't create value and considers whether to eliminate them. Finally, it shows the relationship between the physical flow and the information flow, producing a wider picture of how the organization is operating.

Establish Flow

The value stream mapping shows the obstacles to a continuous flow. This doesn't mean that the organization must work as fast as possible. Continuous flow means that in the organization's material, product, and information flows, there are no stops, waste, or delays, providing the customer the desired product at the requested quality, at the right time and in the right quantity. In pursuing this goal, the organization has to focus on processes instead of a single department and take into account the results of value stream mapping.

In establishing the flow, the analysis and elimination of waste play a key role. Waste is the use of any resource that doesn't create value for the customer. Although not all waste can be immediately eliminated, the organization must detect it and reduce it as much as possible.

Create Pull

According to the Lean Thinking approach, production must be pulled by the client, as opposed to mass production, where the production is pushed from the firm to the client. In the pull principle, activities are performed only if the client expresses a need for them. The client could be external to the firm or a part of it. In the first case, the customer demands finished products or services and in doing this drives the production. In cases of internal clients, an activity begins only when someone along the process needs that activity to begin his work. It means that in a production process, as well as in administrative after-sale services, every operator (part of the process) is at the same time a client and a supplier, as they

receive materials or unfinished work from upstream operators and relay the unfinished work or finished product to other operators downstream. In Lean Thinking, one tool supporting this approach is the Kanban. Kanban are cards in different colors that are used to indicate the pickup of material and, consequently, the need to provide new materials. They show information, for example, the code of the material, quantity to provide and time needed to refill, etc. This tool contributes to avoiding overproduction and is part of the JIT approach.

Seek Perfection

In Lean Thinking, every organization aspires to perfection in all its processes, pursuing Total Quality.

Total Quality management was born in the 1950s in General Motors and is related to the statistical control of product quality and to the studies of Deming (1951) regarding the so-called Deming Wheel. Toyota manager, Ohno, visited General Motors and assimilated these principles but adjusted and re-elaborated them within the Lean approach. In Lean Thinking, Kaizen (continuous improvement in Japanese) plays a key role in seeking perfection and Total Quality (Chiarini et al. 2018). In general, changes in an organization could be realized in two ways: by radical innovations that have a disruptive effect by introducing a completely new reality or by incremental innovation that slowly and gradually improves the organization. The second way is consistent with Lean Thinking and is the essence of Kaizen. The peculiarity of Kaizen is that it is based on the strong involvement of operators in uncovering potential improvements during the processes. Workers are fundamental in detecting waste and activities that don't create value and to find the best way to eliminate them.

These principles explain the core of Lean Thinking, which can be summarized through the goal of rationalizing processes and eliminating waste in pursuing continuous improvement. In this sense, efficiency means both flow efficiency and production efficiency. In the first meaning, a flow is efficient when the throughput time of the process is as close as possible to the cycle time

(sum of the time necessary to perform all the steps of production). Production is efficient when all waste is eliminated.

Even if originally Lean Thinking assumed that workers are one of the most important sources of improvement, this characteristic has gradually become increasingly relevant. The involvement of people is fundamental as on the shop floor as in the whole organization.

In addition to the tools already described (as value stream mapping, Kanban, kaizen, etc.), a useful tool at the operating level is the 5s methodology that indicates the steps needed to optimize the workstation. This tool refers to the following Japanese terms:

Seiri (Sort, Separate): in this step, what is necessary to the activity and what is useful are identified. Because what is redundant or unnecessary is wasteful, it has to be removed.

Seiton (Set, Organize): in this step, what is necessary to the process has to be organized in the best way to achieve flow and production efficiency; order is the key word in this step.

Seiso (Shine, Sweep): this step underlines that keeping the working area clean helps to easily identify problems and find solutions to them.

Seiketsu (Standardize): in this step, the attempt is to define routines and repeatable activities in order to be more efficient in flow and production.

Shitsuke (Sustain): this way of working has to be spread across the organization, eventually with a reward policy to pursue continuous improvement.

Lean Thinking and Sustainability

The topic regarding the relationship between Lean production (or Lean Thinking) and the environment is not new. In 1996, the seminal work of Florida considering previous research pointed out that the adoption of environmentally conscious manufacturing is related to the presence of advanced manufacturing systems (such as Lean production) in various ways. First, the orientation

to reduce the consumption of resources, to improve processes, and to banish waste promotes the goal of reducing emissions and the impact on the environment. Second, Lean product design could be interrelated to Green design. Third, customer orientation (of Lean Thinking) supports a company's increased emphasis on respecting the environment. Finally, the supply chain plays a fundamental role in Lean Thinking and could stimulate positive environmental outcomes (Das 2018).

In the following decades, researchers continued to discuss the argument, accelerating the debate in recent years. The core questions are as follows: (1) how operating within the confines of Lean Thinking could affect or stimulate Sustainability, (2) how being Green or sustainable could affect or stimulate the introduction of Lean Thinking tools, and (3) if and how companies integrate Lean Thinking and Sustainability.

Initially, these questions were focused on Sustainability as being "Green" (Garza-Reyes 2015), but now they are wholly regarding Sustainability in its social, economic, and environmental components (Piercy and Rich 2015; Martinez Leon and Calvo-Amodio 2017).

Since 2014, literature reviews concentrate on attempting to systematize the copious production of article and papers. The editorial of Dhingra et al. (2014) in the special issue of *Cleaner Production* posed the question "Does Lean mean Green?", arguing that Lean leads to Green but not necessarily vice versa and that often the two thinking methods have developed independently. It is relevant to remember that Lean Thinking acts at two levels: (1) the operating level (workplace) and (2) the strategic level (supply chain, organizational impacts). Integrating Lean and Green involves both levels and brings greater benefit to the firm in terms of its productivity and efficiency, as well as its impact on the environment (Strategic Direction 2015).

Recently, the work of Caiado et al. (2018) reported a wide range of literature supporting on the one side "Compatibility" between Sustainability and Lean, and on the other the "Divergences" between them. Compatibility regards, for example, the common goal of reducing waste

(including natural resources, pollution, energy, litter, etc.), people integration as a Lean feature that positively impacts workers and Lean as a catalyst for Green. However, some divergences emerge from the literature. For example, while Lean practices focus on maximizing performance and reducing costs, Green practices attempt to design products for environmental optimization in each stage of the lifecycle; Sustainability is oriented to present and future generations (efficacy, effectiveness, and ethics), while Lean focuses on meeting customer demand in the best way (efficiency, effectiveness); Sustainability considers all the stakeholders, while Lean focuses mainly on customers and the people inside the firm.

Therefore, some common goals and overlap foster a good relationship and interaction between Lean Thinking and Sustainability. However, some areas remain uncovered and could potentially cause trade-offs. For example, in pursuing a process flow and the reduction of stock, a “Lean” firm could have a supply chain with a small yet frequent supply more convenient than having excess stock. However, this choice likely means that there is more of an impact on the environment (fuel, pollution, CO₂) due to the elevated number of trips related to supply.

For this reason, in recent years different authors have proposed an evolution of many Lean Thinking tools in order to take account of the Sustainability dimension, for example, Sustainable value stream mapping, Water flow mapping, Green value stream mapping, etc. (Caldera et al. 2017). As Sustainability orientation is a strategic issue and influences the whole organization, this decision is a big challenge to firms. It requires the organization to shape their Lean Thinking approach at an operational level as well as at its strategic level. First, it means integrating the Lean and Green cultures from top management to all levels and areas. Second, alternatives regarding efficiency and productivity have to be evaluated for their social and environmental impacts. Third, the firm has to enforce the long-term approach, as is coherent with Lean Thinking, extending it to all stakeholders, including future generations. Briefly, it means to build new

business models, integrating Green (or Sustainable) dimensions and a Lean Thinking philosophy (Pampanelli et al. 2015; Cherrafi et al. 2016).

Summary

The path from the seminal principal of Lean to sustainable Lean Thinking has been a long one and illustrates how this managerial approach, born on the shop floor of Toyota, overcame the borders of production, involved the whole organization and expanded out of the automotive sector, and spread across sectors and services. Furthermore, the approach extended to interorganizational relationships, involving suppliers and customers in pursuing efficiency and efficacy. The current challenge to Lean Thinking is not considering the Sustainability dimension to be a complementary part of a Lean approach but rather as an integrated component of it.

Acceptability of operations; Legitimacy of activities; Legitimacy of processes; License to operate; Social acceptance

Definition

Legitimacy is a social value indicating that authorities' legitimate actions facilitate social regulation. Legitimacy is a basic condition of rule to avoid the collapse of a system due to inadequate trust toward it. Authorities and institutions' decision-making processes are commonly assessed by citizens. In this, Tyler's (2001) outcome showed the role of the fairness in the legitimate decision-process. Legitimacy has been considered a

political concept in the research tradition. Within the political legitimacy, Blatter (2021) found similarities between the concept of legitimacy and acceptance of a government. Here, the essential dimensions were political regime and system of governance.

The institutional organization theory (e.g., Powell and DiMaggio 1991) generated the theoretical framework to understand processes to interpret the institutionalization of organizational behavior influencing on organizational concordance with the environment (Oliver 1991), in other words the legitimacy of operations. The globalizing world, tightened legal obligations, and external stakeholder pressure, especially in the 1990s and onward, led to the increasing interest in the acceptability and responsibility of the operations among industries. Businesses aim at reaching more efficient organizational operations through institutional support in the diversifying operation environment. Social, economic, and political factors supporting specific types of activities of a firm create the foundation for an institutional structure of a particular operation environment. Institutionalization supports gaining legitimacy that is needed in strengthening flexible and efficient operations in various environments.

Theoretical and Empirical Research

The concept of legitimacy has been applied largely within various contexts and studied by a number of methodologies. The concept relates closely to the institutional theory. For example, Li et al. (2020) investigated the legitimacy of business contracts. They conclude that elements, such as regulative, normative, and cognitive ones, influence the effectiveness of the layout of a contract and its implementation.

A few recent works investigate legitimacy in the context of managers' moral behavior, multinational business, sustainability certification, and political risks-related business operations. Managers may have different moral principles in establishing the moral legitimacy of business operations. This influences on the environmental sustainability of a firm. Passetti and Rinaldi

(2020) findings suggested that a moral legitimacy is a continuum depending on managerial value basis. The legitimacy is no dichotomous factor, but it varies in time and place due to its value basis. The use of accounting can support the outlining of the legitimacy framework of a firm. The study showed that external disclosure and internal deliberations form together the concept of moral legitimacy in the investigated environment.

The legitimacy of multinational enterprises in host countries is exposed to substantial risks due to the various business, cultural, demographic, and geographical settings. Han (2020) studied mechanisms of risk minimizing in home countries and its influence in overseas operations by multinational enterprises. Furthermore, Wei et al. (2020) concluded that the challenge of the legitimacy of multinational operations lies in the utilization of subsidiaries, especially in emerging markets. They showed that the engagement of political corporate social responsibility (PCSR) activities may cause legitimacy pressure from host countries toward the multinational enterprise.

The relationship between sustainability certifications and legitimate actions was investigated by Feng et al. (2020). They concluded that enterprises have been growingly adopting management practices, such as sustainability certifications. The certification was used in upgrading the legitimacy of operations in order to meet the stakeholders' expectations for sustainable operations, and consequently, to lead a better market value. In environmental and social operations management was an essential part in this.

Policy makers have recognized largely the risk related to the lack of moral and cognitive legitimacy of political actors. Taarup-Esbensen (2019) investigated the political legitimacy and the related political risk, related to environmentally sensitive operations in Greenland. The work concluded that regardless of the relatively large pragmatic legitimacy, business actors did not consider moral and cognitive aspects comprehensively when interacting with Greenlandic politicians and administrative institutions. The outcome showed the benefit of managing political legitimacy in sensitive areas.

Conceptual Framework

The legitimacy of operations is a theoretical foundation related to two operationalized concepts: the acceptability of operations and the license to operate.

The empirical research and business operations have been involved in the concept of acceptability of operations largely since the 1990s. Especially, stakeholders' and other involved people's perceptions were studied largely in the 2000s when aiming to understand the importance of legitimate operations for successful business at the home region and globally. For example, Braam et al. (2016) emphasized the legitimacy in companies' choices, especially related to environmental management and operations. Mikkilä's (2006) findings support this in that the first responsibility initiatives among Finnish industries were based on ad hoc reactions to the case at hand rather than systemized responsibility strategies in international operations from the 1970s to the 1990s (Mikkilä 2006; Mikkilä et al. 2016). The acceptability discussion covered both social and environmental disclosure. The closing down of production units and its consequences to the employees and the society at large reflected the social element of acceptability. Within natural resource-based industries, the acceptable utilization of natural resources was discussed intensively emphasizing the environmental concern. The governmental, nongovernmental, and industrial sectors met a new type of operational challenges in the 2000s when the economic criteria for the acceptable operations expanded to the comprehensive responsibility covering social and environmental issues at large when globalizing industries aimed at reaching general legitimacy for their operations beyond the home country.

Legitimacy of operations at the practical level can be interpreted as a seeking for social license to operate. Social license to operate plays a key role in society in proceeding social norms and superseding legal rules. The concept of social license to operate (SLO) has similar characters with the acceptability of operations in that both concepts have emerged especially within natural resource-based sectors. Gehman et al. (2017) ended to an outcome that SLO was born among

mining, oil, and gas sectors. SLO is a control means to push firms to meet society's environmental expectations. This supports the management of the firm to avoid conflicts and other stakeholder debates that may slow down daily operations. SLO can go beyond the legal obligations (Lynch-Wood and Williamson 2007, p. 322). SLO integrates the working place-connected moral concepts, such as social justice and integrity, but it goes beyond the internal operation environment of a firm by promoting human rights into the business operations (Warhurst 2005). Social license to operate and acceptability of operations are the practical side of the more political and theoretical concept of legitimacy.

Summary

Legitimacy is a social value indicating that authorities' legitimate actions facilitate social regulation. The concept of legitimacy has been applied largely within various contexts and studied by a number of methodologies. The concept relates closely to the institutional theory. The legitimacy of operations is a theoretical foundation related to two operationalized concepts: the acceptability of operations and the license to operate. A few recent works have investigated legitimacy, for example, in the context of managers' moral behavior, multinational business, sustainability certification, and political risks related to business operations.

Organizational legitimization

Definition

Legitimacy theory is one of the most cited theoretical frameworks within social, environmental, and sustainability accounting research. It is probably the most used theory to explain social, environmental, and sustainability disclosure (Campbell et al. 2003, p. 559).

The use of legitimacy theory in sustainability-related accounting research derives from the concept of *organizational legitimacy*. According to Suchman (1995, p. 574), “Legitimacy is a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate

within some socially constructed system of norms, values, beliefs, and definitions.” According to Dowling and Pfeffer (1975, p. 122), this is “a condition or status which exists when an entity’s value system is congruent with the value system of the larger social system of which the entity is a part. When a disparity, actual or potential, exists between the two value systems, there is a threat to the entity’s legitimacy.”

Legitimacy theory postulates that organizations “continually seek to ensure that they operate within the bounds and norms of their respective societies. In adopting a legitimacy theory perspective, a company would voluntarily report on activities if management perceived that those activities were expected by the communities in which it operates” (Guthrie and Ward 2007, p. 4).

Introduction

Legitimacy theory cannot be simply considered as a “theory” applied to sustainability-related accounting research since there are two main classes of legitimacy theory. According to Tilling (2004a, p. 2), it is possible to distinguish between:

1. A wider perspective, addressing the “macro-theory” of legitimation, also called “institutional legitimacy theory”
2. A narrowed perspective, operating at the organizational level, also called “strategic legitimacy theory”

The former approach examines how organizational structures considered as a whole (e.g., government or capitalism) have gained acceptance from the broad society. Within this approach, *legitimacy* and *institutionalization* can be considered as synonymous. Both of them enrich organizations since they look as natural and meaningful (Suchman 1995, p. 576). This approach examines legitimacy by the “institutional level,” focusing on the role of government, religion, society, and capitalism. In this approach, the business environment (which includes the democratic government and the capitalist structure) is considered as a static element within the examined context.

The latter approach examines legitimacy from the perspective of individual organizations. This is the approach most addressed by accounting research (Tilling 2004a, p. 4). Organizational legitimacy is here considered as an operational resource that organizations need to achieve their goals (Suchman 1995). Organizational legitimacy can be enhanced by some events, such as environmental-oriented organizational behavior or the disclosure of positive information about the organization. On the other hand, organizational legitimacy can be undermined by other events, such as financial scandals, major accidents, etc. According to this perspective, organizations “seek to establish congruence between the social values associated with or implied by their activities and the norms of acceptable behavior in the larger social system in which they are a part. In so far as these two value systems are congruent we can speak of organizational legitimacy. When an actual or potential disparity exists between the two value systems, there will exist a threat to organizational legitimacy” (Mathews 1993, p. 350).

In the narrowed perspective, legitimacy is considered as a resource necessary to operate, just like money. Organizations should act carefully since some actions and events can increase their legitimacy, while others can decrease it. This is a very relevant aspect to be considered, since a significant decrease in the organization’s legitimacy could ultimately determine the loss of its right to operate. In other words, the existence of a sufficient level of legitimacy is a necessary condition for the *durable survival of the organization*.

The two abovementioned perspectives of legitimacy theory are outlined in Fig. 1.

The theories used in corporate social responsibility (CSR) and sustainability literature can be categorized in the following categories:

- Economic theories, which focus only on the economic aspects of CSR and sustainability issues, with specific reference to financial stakeholders interests
- Social and political theories, which focus mainly on CSR practices

Legitimacy Theory,

Fig. 1 The two perspectives of legitimacy theory. (Source: Tilling 2004b, p. 3)

The former include decision usefulness theory, agency theory, and positive accounting theory, while the latter include legitimacy theory, stakeholder theory, and institutional theory.

Main Aspects of Legitimacy Theory

According to legitimacy theory, the legitimacy of an organization (e.g., a business entity) to operate within a society depends on an *implicit contract* between the organization and the society. If the organization does not respect the society's norms and expectations, it can lose its license to operate. In this perspective, organizations decide to voluntarily report on their activities if these activities are expected by the community of reference (Deegan 2002).

The concept of *social contract* is very relevant in legitimacy theory. It has been described in these terms (Shoker and Sethi 1973, p. 67): "Any social institution – and business is no exception – operates in society via a social contract, expressed or implied, whereby its survival and growth are based on:

1. The delivery of some socially desirable ends to society in general; and
2. The distribution of economic, social or political benefits to groups from which it derives its power."

The concept of social contract implies the existence of various expectations of the whole society

about the organization's conduct and operations (Deegan 2000; Mathews 1993). To survive over time, society should perceive that the organization has breached its social contract (Deegan 2002). If society is not satisfied about the organization's activities and operations, it will revoke the social contract, thus implying that the organization can no longer operate (Deegan and Rankin 1997). This could happen in various forms, e.g., customers may reduce the demand for the organization's products; the organization's suppliers may reduce or eliminate the supply of labor and financial capital; and laws could prohibit the actions which do not conform with the community's expectations (Deegan 2002).

Since social expectations change over time, also the terms of the social contract are not stable and permanent, changing over time. This means that the organizations' needs to disclose about their activities also change over time. In the case the community of reference deems the social contract has been breached, organizations should enact remedial actions necessary to guarantee their lasting survival over time. Among these remedial actions, legitimacy theory provides the notions of "legitimacy gap" and "legitimacy strategies." These concepts are described in the following:

- (a) According to Lindblom (1994), a "legitimacy gap" is the difference between the expectations of the community (and more in detail of the relevant stakeholders) about how an

organization should act and how the organization does act. A legitimacy gap creates a threat to the organization's legitimacy. "In the view of the Legitimacy Theory (Lindblom 1994), for listed companies, the increased pressures coming from the external environment also have to be considered, given their importance in terms of both positive and negative impacts, on the context considered as a whole. In this perspective, the purpose of sustainability reporting is to fill the legitimacy gap until the desired level is achieved (Lindblom 1994), pursuing the objective of increasing, maintaining and restoring the consensus by the stakeholders. Their consensus is a necessary condition to act effectively in the socio-economic context in which they operate. Communication is the most important element for the legitimation within the reference environment and for the approval of the stakeholder [...]. Being socially responsible is not enough to legitimize oneself, it is also required to communicate the objectives, the actions and the results obtained [...]. Accordingly, sustainability reporting is an aspect of particular importance for the legitimacy processes, contributing to improve the transparency in the relationships and to increase the credibility and the confidence between the community and the stakeholders" (Vitolla and Rubino 2017, p. 1915).

- (b) If managers perceive that the organization's operations are not in tune with the social contract, they activate remedial actions aimed at becoming legitimate (Dowling and Pfeffer 1975). Since legitimacy theory is based on stakeholders' perceptions, these remedial actions should be publicized through an appropriate disclosure (Cornier and Gordon 2001; Deegan 2002).

According to Hybels (1995, p. 243), "Legitimacy has often been conceptualized as simply one of many resources that organizations must obtain from their environments. But rather than viewing legitimacy as something that is exchanged among institutions, legitimacy is better conceived as both part of the context for exchange and a by-product

of exchange. Legitimacy itself has no material form. It exists only as a symbolic representation of the collective evaluation of an institution, as evidenced to both observers and participants perhaps most convincingly by the flow of resources."

According to Hybels, it is important to identify the relevant stakeholders in legitimacy theory since each of these stakeholders influences the resources necessary for the organization's establishment, growth, and survival. In his opinion, four main critical organizational stakeholders control different resources:

1. *The state*, which controls contracts, grants, legislation, regulation, and tax
2. *The public*, which controls patronage (as customer), support (as community interest), and labor
3. *The financial community*, which controls investments
4. *The media*, which controls some direct resources and can influence stakeholders' decisions

Focusing specifically on *organizational legitimacy theory*, there are four phases in which an organization (e.g., a firm) could be, i.e.:

1. *Establishing phase*: this is the first phase of the legitimacy's cycle. It is an early phase of the organization's development, in which it is important that the organization focuses on financial competence, quality, and desirability and that it operates under accepted standards of professionalism (Hearit 1995, p. 2).
2. *Maintaining phase*: this is the phase in which most organizations operate. In this phase, main organizations' activities include "(1) ongoing role performance and symbolic assurances that all is well, and (2) attempts to anticipate and prevent or forestall potential changes to legitimacy" (Ashford and Gibbs 1990, p. 183). The maintenance of legitimacy is almost complicated to achieve, as community expectations are non-static, but change frequently over time. Therefore, organizations should promptly react to the change of expectations in their environment of reference.

3. *Extending phase*: an organization could operate within a phase where it is necessary to extend its legitimacy, e.g., if it is entering in new markets. In this case, management should try to win the confidence and support of different potential constituents (Ashford and Gibbs 1990, p. 180).
 4. *Defending phase*: in this phase, the organization's legitimacy is threatened by an incident (internal or external) and requires specific defense activities. Most accounting research on organizational legitimacy focuses on this phase.
 2. Seek to change the perceptions of the relevant stakeholders without changing its actual activities and performances.
 3. Seek to manipulate the stakeholders' perception deflecting their attention from the problematic issue to other more appealing issues.
 4. Seek to change the stakeholders' expectations about the organization's performance.
- More in detail, these four strategies can be used under these conditions:

Key Issues

This entry examines legitimacy theory with specific reference to sustainability-related accounting research. Under this perspective, there is a strong relationship between legitimacy theory and voluntary disclosure. Campbell et al. (2003) focused on the role of voluntary disclosure in attempting to close a perceived legitimacy gap. According to their contribution, levels and patterns of voluntary disclosure may vary depending whether the organization's products:

- (a) Have negative connotations (e.g., tobacco companies, whose production is usually considered as illegitimate)
- (b) Have not negative connotations, but produce some undesirable by-products

In the first case, the organization probably cannot get legitimacy in the eyes of its stakeholders. In this case, disclosure will simply tend to limit the damages associated with the bad organization's image and convince stakeholders that the organization is "not all that bad."

In the second case, disclosure can be used to improve the organization's image.

According to Gray et al. (1995), if the organization's management believes the organization's legitimacy is threatened, it can adopt the following strategies:

1. Seek to educate and inform the relevant stakeholders about actual changes in the organization's activities and performances.

1. The first strategy is the answer to a "legitimacy gap" emerging from a failure of the organization's performance.
2. The second strategy is the answer to a legitimacy gap emerged as a consequence of a misperception of some relevant stakeholders.
3. The third strategy is the answer to a manipulation.
4. The fourth strategy is the answer to unrealistic or incorrect stakeholders' expectations about the organization's responsibilities.

Future Directions

Legitimacy and stakeholder theories assume that the disclosure of financial, social, and environmental information (such as corporate social responsibility or sustainability reports) is a relevant part of the dialogue between the organization and its stakeholders. This disclosure is very relevant since it helps legitimize the organization's behavior and influences perceptions and expectations of relevant stakeholders (Adams and Larrinaga-González 2007; Adams and McNicholas 2007). According to legitimacy theory, there is a strong relationship between sustainability-related disclosure and the organization's *reputation*. The latter can be understood under three main aspects (Michelon 2011):

1. Commitment to stakeholders (Ullmann 1985; Unerman and Bennett 2004)
2. Financial performance (Roberts and Dowling 2002; Deephouse and Carter 2005)
3. Media exposure (Erffle and McMillan 1990; Neu et al. 1998).

Sustainability-related disclosure could be used by organizations to manage their reputation risk (Bebbington et al. 2008), thus projecting a socially accountable image (Gray et al. 1995). As a consequence, the organization can increase its legitimacy and manage its reputational risks (Bebbington et al. 2008; Fombrun et al. 2000). According to Michelon (2011), *reputation* is a determinant of sustainability disclosure, and it has main points in common with the concept of legitimacy. According to Friedman and Miles (2001), reputation is a determinant of sustainability disclosure since organizations communicate to external stakeholders their engagement with social, environmental, and sustainability issues.

Also *signaling theory* is useful to explain the reasons why organizations engage in sustainability-related reporting. It assumes that organizations use this type of communication to signal their reputation to the relevant stakeholders.

Further research deserves attention to the differences and the relationships between *legitimacy* and *reputation*. The former can be defined as “the generalized perception or assumption that the action of an entity are desirable, proper and appropriate” (Suchman 1995, p. 573), while the latter is considered as a synonymous of image, prestige, and esteem (Shenkar and Yuchtman-Yaar 1997). According to Deephouse and Carter (2005, p. 331), reputation is associated with the relative position of an organization among its counterparts. Legitimacy theory could therefore be used in the future to explore also the concept of reputation.

Summary

The chapter structure is organized as follows: firstly, a definition of legitimacy theory in the context of sustainability-related accounting research is provided. The introduction explains the existence of two main classes of legitimacy theory (i.e., the “institutional legitimacy theory” and the “strategic legitimacy theory”). Thereafter, the main aspects of legitimacy theory are described. The subsequent two sections address the key issues and future directions. Cross-references and references close the chapter.

Legitimacy Theory II: Legitimacy Judgments

Deike Schulz

Institute of Management Research, Radboud University, Nijmegen, The Netherlands
Academy of Communication and Creative Business, NHL Stenden University of Applied Sciences, Leeuwarden, The Netherlands

Synonyms

Consumer judgments; Evaluative judgments; Legitimacy judgments

Definition

Legitimacy judgments address how actors individually or collectively are able to judge organizations and their legitimacy supportive or defensive actions, through their (written and/or spoken) evaluations. Through these evaluations, organizational legitimacy can be (dis)supported. Non-organizational actors who provide evaluative judgments can do this un(invited) and via various (media) channels. For example, media organizations such as newspapers or news websites can review a sustainable organization and put forward how “legit” an organization is on the basis of their evaluation of the organization, its products, services, and action. Additionally, an individual Facebook user can judge an organization by sharing his or her personal experience with family, friends, or colleagues. Moreover, a blogger can share and discuss his or her evaluation about an organization with like-minded individuals who are able to provide comments on this blog post. This can influence how sustainable organizations

and their products or services are judged and (dis) accepted by the general public. Consequently, legitimacy judgments are closely related with organizational legitimacy theory as they provide insights on how legitimacy management is evaluated by non-organizational actors.

Introduction

Organizational legitimacy (see entry ► [“Organizational Legitimacy”](#)) and/or by itself is how actors from the (in)direct environment perceive and approve an organization as a whole. Organizations construct or manage legitimacy in order to be accepted as “good” organizations by actors that “observe” the organization and its actions (Suchman 1995). Construction of legitimacy concerns the process of “legitimation” (actions or steps) through which an organization strives to be accepted by its environment. To illustrate an organization can manage legitimacy by sharing their sustainability reports or by responding to customer questions via their Twitter account in order to manage legitimacy.

Legitimacy is often discussed as an organizational asset or property; however, legitimacy can also be seen as a judgment about an organization and its products, services, and actions provided by individuals on the micro level as well as groups of actors on the macro level (Bitektine and Haack 2015). Individuals may (dis)approve of an organization by evaluating its current approach to sustainability, for example, by searching for information about this organization or by reading about it in a newspaper or online platform. This evaluation may lead to a judgment shared privately or in the public domain with other actors, which in turn may influence how other stakeholders perceive the organization being judged in the long run. As such legitimacy is also constructed by external stakeholders through their evaluative judgments. This evaluator perspective on legitimacy has been introduced and discussed in recent years in the management literature (Bitektine and Haack 2015; Deephouse et al. 2017; Tost 2011). With regard to sustainability, legitimacy judgments have been addressed in cases such as the

credibility of the Canadian oil sands industry (Finch et al. 2015) and the negative influence of online protest on organizations, their brand image, and the purchase intentions of consumers (van den Broek et al. 2017).

Key Issues

Evaluative judgments can be constructed through various channels and by various actors. More importantly individuals may validate their evaluation of an organization by comparing it with the judgment of other individuals or by consulting public judgment validation institutions. Bitektine and Haack (2015, p. 54) mentioned three essential judgment validation institutions:

- Media (e.g., journalists’ or experts’ judgments via online or offline media)
- Government (regulators’ judgments)
- Judicial system (jury and judges’ judgements)

These institutions are seen as critical sources of validity that are able to influence the judgments of others. For example, journalists can evaluate how much effort a food company puts into waste management in order to become more sustainable and can point to misleading practices, such as greenwashing. Experts can reflect in the public domain on the actions of a company in becoming more sustainable. Regulators can develop waste management monitoring or certifying systems that support their evaluation of an organization in that area, and judges can evaluate if the current approach of an organization adheres to the law.

In addition to these public judgment validation institutions, individuals can also validate their evaluations via online communities. Actors are able to share their thoughts through the exchange of written and audiovisual content with like-minded individuals (see entry ► [“Online Communities”](#)). Together with others, they produce online-mediated evaluative judgments which are “... written messages, images, or audiovisual material – that a group of citizens produces, shares, and mediates via online communities outside the direct influence of a company. Essentially,

online-mediated OL judgments made through online communities extend OL from a company or individually driven process into a multilevel system in which citizens construct OL collectively” (Schulz et al. 2018, p. 292).

For example, a customer can share his or her thoughts about an organization in a Facebook post or in a personal review on a blog or YouTube video. Individual actors with many “followers” on such social media platforms, so-called influencers, can become influential evaluators, due to the reach of their shared evaluative judgments which may influence their followers’ perception of an organization. Consequently, evaluative judgments produced by influential individuals, as (dis)approval of an organization may lead to a collective consensus about said organization within a group of actors and may influence the evaluation of each individual following and participating in such a community. These influential individuals can be seen as experts, by their followers, as they may attract and influence a large group of individuals who consult their media channel to validate their evaluation of an organization and its products, services, and actions. A topic introduced by such an influencer can trigger feedback from many other individuals interacting with each other and discussing such a topic or sharing the topic with others outside the community. Online communities therefore function as informal public judgment validation institutions.

Groups of actors, for example, activists’ groups can collectively respond to information shared by an organization in order to manage its legitimacy. These actors can share their thoughts and opinions through various media channels or in online communities. In addition, organizational issues can be brought to light or can be discussed within those online communities, for example, by fans of a certain brand or product category such as sustainable food or cosmetics. Actors in such communities can collectively judge organizations by providing feedback on questions from others about that particular organization or by introducing organizational information or their first-hand experience with its products or services.

Summary

Evaluative judgments rendered by individuals or groups can influence organizational legitimacy in a positive or negative way. Right now, social media platforms such as Twitter or YouTube are becoming increasingly important for organizations in constructing and defending legitimacy. Consumers are able to influence legitimacy through their evaluative judgments, for example, through ratings and comments on organizations via Google Maps. However, organizations are also able to approve or defend evaluative judgments coming from non-organizational actors through their own or public social media platforms, online communities, or other media channels such as the press. As a consequence, organizations have to become more proactive in dealing with and responding to evaluative judgments. Moreover, they have to accept that non-organizational actors are part of the legitimization process that can construct legitimacy through their evaluative judgments independently and uninvited.

Another important challenge regarding evaluative judgments in the future is the growing influence of technical developments such as artificial intelligence (AI). AI, for example, chat robots or avatars, will come into play via online (social media) platforms. These technologies will be able to evaluate organizations on the basis of automated replies via websites, e-mails, or social media channels, hosted by AI influencers “puppeteered” by technology companies. For example, through avatars such as Lil Miquela, an Instagram influencer with more than one million followers, who is not a real person but engineered by a US technology start-up (Petrarca 2018). Such developments are also closely related to issues around “fake news,” which concerns all misinformation that is publicly shared and re-shared by individuals, groups, and other organizations. Finally, these developments show that individuals may, next to the press, government, and law representatives, consult informal public judgment validation institutions such as online communities in order to validate their evaluation of an organization.

On that account organizations have to become more aware of whom, how, and where evaluative

judgments about their organization are shared. Analyzing and understanding individual as well as collective (human and artificial) legitimacy judgments is key here as these judgments will be shared via various channels and will echo online and offline by means of other individuals and groups re-sharing written and audiovisual content.

Description

Life cycle assessment (LCA) methodology is a standardized method for assessing the potential

environmental impact of a product or service throughout its lifetime (ISO 14040). As such, it represents a valuable tool by which researchers and organizations can identify, and avoid, unnecessary environmental burdens that have a negative impact on the ecological health of the globe. Environmental sustainability challenges mainly stem from humanity's current production and consumption habits. In this regard, there is a need to develop production practices and consumption behaviors that support sustainable development. It is imperative that we find solutions by which we can reduce environmental impacts and resource use within production chains. The first ISO standard for LCAs was published in 1996, and updated versions 14040 and 14044 were published in 2006. These LCA standards act as valuable guidelines and standards by which practitioners can reduce their (Klöppfer and Grahl 2014) carbon footprint and product environmental footprint. It also acts as a tool that can support decision-making pertaining to various questions related to the environmental impacts of products and systems.

Introduction

The LCA methodology was developed as a means of evaluating the impact that a product has on the environment throughout its life cycle. The method aims to define the environmental effects of the whole production and distribution system, the most significant environmental impacts, and the most significant life cycle phases related to the most significant environmental impacts.

The contemporary economies of the majority of industrial countries are predominantly based on a take-make-and-dispose system, even though recycling practices have recently been developed in many countries. This take-make-and-dispose system relies on humanity having access to ready forms of resources and energy, a sufficient number of sinks for waste, and enough money to cure the adverse environmental impacts (Webster 2016, p. 332). However, although our current way of living is established on these grounds, we cannot continue along this route.

Climate change, the diminishing quality of air in cities, and lack of arable land are examples of the sustainability challenges that humankind is facing. The magnitude of these sustainability challenges is continuing to expand due to the growing number of people in the world, the increasing number of middle-class people, and rising consumption.

The challenges mainly stem from the current production and consumption habits. Market liberalization has shifted production to regions in the world in which the cost of labor and commodities is significantly lower than that on offer in developed countries. In many cases, this mainly results from a lack of legislation that protects the environment, workers, and stakeholders in low-cost manufacturing economies. However, the sustainability challenges are not limited to less-developed nations. Global environmental challenges, like climate warming, are not dependent on where the impact is produced. Besides existing consumption habits, trends like urbanization and increasing standard of living have incurred unexpected environmental implications in developed countries.

Due to the length and scale of production chains and the ever-more complicated production processes involved, it is imperative that any evaluation of environmental impacts spans the end-to-end life of a product, from raw material through to disposal. The LCA was developed to utilize database information pertaining to the existing processes in which the event measurement data is not available or is considered too expensive to compile. LCAs also allow the use of calculated or estimated data if such information is determined to be in line with the use purposes of the results. Therefore, LCAs are recognized as one of the best methodologies for the evaluation of the environmental impacts of products (Cherubini et al. 2009).

A Brief History of the LCA

In the 1960s, people were mostly unconcerned about the sustainability of economic growth. However, gradually, as energy consumption

rapidly increased, waste disposal issues became more common, and evidence started to emerge that industrial manufacturing was causing air and water pollution; questions concerning resource use and energy consumption emerged throughout the product chain.

As a result, in cooperation with the scientific community and industry representatives, developed a methodology that could be employed to the assess resource and energy use, solid waste disposal, and pollutants associated with a manufactured product. This methodology was referred to as resource and environmental profile analysis (REPA), and it was inspired by material flow accounting (Klöpffer and Grahl 2014, p. 7). The first applications of the methodology were focused on chemical intermediates and beverage packages at the 1960s (Bjørn et al. 2018). The sufficiency of resources came under further public scrutiny following the Club of Rome's report titled *Limits of Growth* in 1972 (Klöpffer and Grahl 2014, p. 7). This report assessed the connection between economic growth and sufficiency of material and energy resources. At the same time, the oil crisis also turned the discussion toward the efficient use of resources.

Public and academic awareness of the environmental impacts of production increased as evidence about the depletion of the ozone layer, climate change, acidification, and eutrophication emerged. Consequently, it was necessary to develop the REPA methodology so that it could quantify resource use and emissions while also assessing the environmental impacts and ecological consequences associated with a product throughout its life cycle. This was somewhat challenging as, in most cases, the uncertainties related to environmental sustainability increase exponentially the further the point of evaluation is from the actual source of emission. Therefore, as a starting point to assist studies that incorporated environmental impact assessments, the so-called midpoint approach was developed. This approach was justified by the fact that, in many cases, it is more important to assess the potential for environmental impacts without increasing the uncertainty that is inherent in the results.

The first international ISO standards pertaining to LCA were published in 1996, and they also included the impact assessment phase. The assessment of environmental impacts continued to evolve alongside the emergence of new findings in the scientific context. For example, the environmental assessment of chemicals benefitted ecotoxicology (a science developed for assessing the effects of toxic chemicals derived from natural or synthetic sources on biological organisms). Even after the publication of the international LCA standards, the methodology was scarcely utilized among industry representatives primarily because the formative applications were still considered to be too resource intensive and, as such, the costs outweighed the benefits of any LCA assessments. The approach involved typically consisted of a bottom-up method that aimed to collect nearly all the input and output data from the production chain before identifying the main environmental impacts and the life cycle stages at which those impacts could be observed. However, the uncertainty regarding some impact category data and the inconsistency in data quality related to alternative product chains frequently led to the conclusion that the methodology was still in its infancy. After 10 years, the updated versions were released, and a top-down approach was recommended by which the focus of the study was firmly placed on reducing resources.

Throughout these developments, awareness of the sustainability challenges continued to grow, and the need to help customers to choose more sustainable products and services was increasingly recognized. As a result, the first instructions to calculate carbon footprint for products and services, called PAS 2008, were published in the United Kingdom in 2008. The guidelines were developed based on LCA standards, but as they were purely focused on climate change, they were precise.

The introduction of carbon footprint calculation standards clearly increased the demand for LCA-qualified professionals. It also encouraged the development of the widely accepted international standards, and, in 2012, the first international standard "Product Life Cycle Accounting and Reporting Standard" was published by the

GHG Protocol after businesses, governments, and other bodies convened at the World Resource Institute (WRI) and World Business Council for Sustainable Development (WBCSD). Two years later, the first carbon footprint ISO standard was published (ISO 14067:2013).

The popularity of the carbon footprint standards also instigated the development of other footprint methodologies by which the issues threatening sustainability could be addressed. The Water Footprint Standard ISO 14046 was released in 2014. It was based on the LCA ISO standards and the carbon footprint ISO standards. A nutrient footprint methodology has also since been developed, and some publications are already available in scientific forums (e.g., Grönman et al. 2016; Leach et al. 2012; Metson et al. 2012). Land footprint suggestions have also been presented, but scholars have yet to agree on a universal definition of land footprints. Generally speaking, during the last decade, land use-related impacts have been acknowledged as representing one of the main challenges in LCAs, as the methodology was initially developed to assess industrially manufactured products and services. In more recent times, researchers have turned their attention to developing LCA-based handprint indicators.

LCA Methodology

The LCA is a tool that can be used to assess the environmental impacts a product incurs during its life cycle (ISO 14040). The method is structured, comprehensive, and internationally standardized (Väisänen 2014). There is broad agreement in the scientific community that LCAs represent one of the best methodologies for the evaluation of environmental loading associated with product and services (Cherubini et al. 2009). An LCA is used as a basis for many other applications, like the carbon and water footprint and the product environmental footprint (PEF) guidelines, which provide more detailed information about the calculation principles associated with these specialized applications than the original LCA standards.

Both environmental aspects and potential environmental impacts across the full life cycle of the product are studied in the LCA. One of the main objectives of the LCA method is to employ a systematic overview and perspective to avoid shifting the environmental burdens from one life cycle stage to another or from one process to another. Typically, the LCA does not address economic or social aspects, although the life cycle approach and methodologies may also be applied to them (EN ISO 14044:2006). The LCA method is defined by the international standards ISO 14040 and ISO 14044, and these standards focus on environmental impacts. Therefore, the overview of the methodology provided in this entry relates to these standards.

In an LCA, the life cycle of a product is modeled as a product system that performs at least one defined function. The essential feature of a product system is demarcated by its function, and it contains the processes that are required during different life cycle phases. These processes are linked to each other by flows (intermediate products, waste, products, or elementary flows). An example of a product system is presented in Fig. 1 (Väisänen 2014).

Following the guidelines given in the ISO standards 14040 and 14044, an LCA involves four steps: goal and scope definition, life cycle inventory (LCI), life cycle impact assessment (LCIA), and life cycle interpretation (ISO 14040). These four steps are presented in Fig. 2.

The first step in the LCA is goal and scope definition (ISO 14040). During this phase, the purpose and nature of the study are defined together with the target group of the outputs. The goal definition outlines the basis for the research and the framework under which it is performed. It is also essential to describe how the results will be employed in comparative assertions that are intended to be disclosed to the public because this has implications in terms of the study requirements and how the findings will be critically reviewed during the results interpretation phase. Since LCA studies form a part of a more extensive decision-making process, it is crucial to clearly define what role the results are anticipated to play or how these results should be viewed. The LCA

Life Cycle Assessment, Fig. 1 Product system (ISO 14040:2006)

Life Cycle Assessment, Fig. 2 LCA framework (ISO 14040:2006)

is a scientific method by which potential environmental impacts can be assessed; however, it does have some inherent limitations that entail that the outputs can be considered to be representative of the whole situation. Therefore, it is vital to define the extent of the usability of the results. If the report is intended to inform a new policy or regulation, it will be underpinned by very different requirements to those that are designed to help a

company decide the environmental implications of one of its processes. The data requirements and sensitivity will also vary across these two instances, and, as such, the resources required to complete the LCA will also vary.

Determining the scope of the study involves setting the system boundaries in the form of a flow diagram. Dividing a product system into its components in the form of processes and flows facilitates the identification of the inputs and outputs of the product system (Väisänen 2014). The boundaries and the level of modeling are designed to ensure that the goal is achieved (ISO 14040:2006). LCA, as the name suggests, is the study of the entire life cycle of a product. When an LCA is carried out, usually all phases of the life cycle are considered, including material acquisition from environment, material processing and transportation, production of the product, distribution to users, use, reuse, maintenance, and disposal, at which point the materials have no use value (see Fig. 1). When the entire life cycle is considered, the approach can be referred to as a cradle-to-grave assessment. Sometimes the questions that an LCA aims to answer do not require modeling the entire life cycle; in such cases a partial LCA can be performed. In a partial LCA, the system under study is limited from the beginning or the end: cradle-to-gate, where the assessment ends after the production phase, or gate-to-

grave, where only use phase and recycling or disposal are considered. In fuel studies, well-to-wheels, well-to-tank, or tank-to-wheels are used to describe the system boundary settings.

LCA is a relative approach (ISO 14040:2006) that can be used to compare one system to another (Fava 2005). It is designed around the functional unit of a product or service, which originates from the function of the studied service or product. The functional unit describes the object of the study, and the second step in the LCA, inventory analysis, is carried out based on the functional unit and the corresponding reference flow, which indicates the amount of product required to fulfill the defined functional unit (ISO 14040; Fava 2005).

The goal and scope of an LCA should be consistent and defined based on the intended application of the study. The LCA has an iterative nature, and, thus, the scope may need to be refined during the study (ISO 14040, ISO 14044). Two different approaches to an LCA are presented in the ISO 14040 standard. The first assigns flows and potential environmental impacts to a specific product system, while the second studies the environmental consequences of possible (future) changes between alternative product systems (Väisänen 2014). The intended use of the first approach could be, for example, environmental footprints, and the second approach can be used, for example, when the interest is to examine the potential environmental impacts of decisions concerning large systems, such as switching from partly fossil-fueled electricity production forms to renewables on a system scale.

The goal and scope definition of an LCA forms a foundation for inventory analysis (LCI). In the LCI analysis, data for input and output flows from the processes that form the studied product system are collected (Fig. 3). LCI analysis gives the inventory of the input and output flows of the studied system, which transition across the system boundary. These results are described in the form of numerical values and cover the entire life cycle. In other words, the inventory flows that cross the system boundary line can be used as a basis for the impact assessment phase (LCIA). The results are presented, for example, in the form of kg/functional unit or MJ/functional unit depending on the

Life Cycle Assessment, Fig. 3 For LCA input and output flows of the system under study need to be defined (Klöpffer and Grahl 2014)

type of flow. During the data collection process, it is crucial to collect the data to such an extent that the study requirements defined in the goal and scope definition phase are met (Köppler and Grahl 2014). For example, if the study aims to assess global warming impact, it is important to collect all the flows that have an influence on this impact category. In this way, the goal and scope definition helps to ensure that the study remains focused on the relevant information and there is no unnecessary data collection.

The third step in the LCA is impact assessment, during which the data produced during the LCI are assigned to impact categories (e.g., climate change, eutrophication) (Klöpffer and Grahl 2014). The impact categories and characterization models will have been specified earlier within the scope definition. This process, during which the input and output flows are connected to relevant impact categories, is called classification (ISO 14044). The impact assessment phase includes three mandatory elements: (1) selection of impact categories, category indicators, and characterization models; (2) classification; and (3) calculation of category indicator result (characterization) (Fig. 4) (Klöpffer and Grahl 2014). After the characterization, the results are presented in the unit of characterization model category indicator, for example, with the values of kgCO₂-eq./functional unit when the IPCC model for the global warming is selected as a characterization model. The selections need to be justified and consistent with the goal and scope of the LCA.

In addition to these mandatory elements, the ISO 14044 standard presents four optional features: normalization, grouping, weighting, and data quality

Life Cycle Assessment, Fig. 4 Phases of the life cycle impact assessment (Klöppfer and Grahl 2014)

analysis. During these phases, the results after the mandatory phases are further processed to facilitate the interpretation of the findings. During the normalization, the characterization results are compared to some reference information, and this phase can provide information about the relative importance of the LCIA result. For example, the reference information can be the emissions produced in a particular area. In this case, the results will be normalized in the form of % of emission of one area. In the grouping impact, categories are assigned either by sorting them on a nominal basis or ranking them according to a given hierarchy (e.g., high, medium, and low priority). In the weighting, numerical factors based on value choices are used to change the order of the impact assessment results in a way that some impact categories are weighted higher than others. During the weighting exercise, the results can be aggregated to one single value, such as in the guidelines of product environmental footprint guides (Fig. 5). Identifying a single value that will be used to measure all environmental impacts within a system makes it more straightforward to compare the systems because the weighting steps are based on value choices; the result is not

scientifically based. The last optional element, data quality analysis, studies the significance, uncertainty, and sensitivity of the LCIA results and can include Pareto analysis, uncertainty analysis, and sensitivity analysis (ISO 14044). When these methods are employed, reliability of the results and, impact of selection of data or assumptions to the LCIA results will be understood better.

The fourth and the last step in LCA is interpretation. During this phase, conclusions are drawn from the previous LCI and LCIA results, and recommendations are developed in line with the study objective. During the interpretation phase, all assumptions, including the boundary conditions, should be once again critically assessed (Köppler and Grahl 2014). In the interpretation phase, the quality of data and applied method sufficiency to support the results need to be examined and documented. The regulations are stronger if the LCA is to be used for comparative assertions that will be made publicly available. In such a case, there is a requirement for the outputs to undergo a critical review by internal or external experts or a panel of interested parties, as stated in ISO 14044. Additional requirements and

Life Cycle Assessment, Fig. 5 Results can be aggregated to a single aggregated value by using weighting factors for environmental impact category indicator results

guidance for third-party reports are provided in the ISO 14044 standard.

Different Applications: Footprints, Ecodesigning, and Ecolabelling

From the environmental sustainability point of view, it is necessary to identify the most reasonable solutions not only in terms of product development options but also when comparing alternative system solutions to cover energy needs, water supply needs, or waste treatment needs, among others. In applications of this nature, the LCA supports decision-making and aims to find answers to questions such as the following:

- Is the proposed system more environmentally sustainable than the original one?
- Is the proposed system more environmentally sustainable than its competitors?
- Could the environmental impact of the product chain be reduced if alternative raw materials are used?
- Could the environmental impact of the product chain be reduced if alternative manufacturing methods are used?

- Could the environmental impact of the product chain be reduced if a life cycle stage is located in a country that has abundant water resources?
- Could the environmental impact of the product chain be decreased if the processing phase delivers a more effective way of utilizing secondary flow?

In recent times, product packaging increasingly incorporates footprint labels that help consumers choose the most sustainable product. Footprint calculations consider the whole life cycle, and the calculation ISO standards (ISO 14067:2018 carbon footprint, ISO 14046:2014 water footprint) are based on the LCA ISO standards of LCA (ISO 14040:2006 and ISO 14044:2006). The carbon footprint standards provide more detailed instructions on how to calculate the greenhouse gas emissions of a product chain for communication purposes.

To support environmentally conscious decision-making at a consumer level in the European Union (EU), the EU has introduced new directives (Ecodesign Directive 2009/125/EC, Energy Labelling Directive 2010/30/EU). The aim of these directives has been to encourage manufacturers to direct their attention to the product design phase, which is estimated to determine more than

80% of the environmental impacts of a product (Wenzel et al. 1997). The Ecodesign Directive aims to improve the environmental performance of energy-related products throughout their life cycle. At present, the main focus is on energy efficiency during the use phase; however, based on estimations, in the future, more and more demands have to be set to other environmental aspects as energy consumption decreases and life span of electronics gets shorter (Dalhammar and Machacek 2013).

Significant effort has been invested in the development of LCAs that cover additional sustainability concerns, including social and economic dimensions. This would be especially important in cases that involve developing existing product chains to enable them to fulfill the sustainability expectations of a company's stakeholders.

Discussion

Business Motivation to Conduct a Life Cycle Analysis

The primary motivating factors that encourage companies to carry out LCA studies are cost savings and profitability. Besides considering environmental aspects, economic aspects are of significance because they influence the extent to which an investment is sustainable over a longer-term period (Ristimäki et al. 2013). In parallel to an LCA, life cycle costing (LCCA), environmental life cycle costing, or social life cycle costing (SLCC) can be carried out to provide more information about the risks that may arise in the near future or within a non-limited time frame (Hunkeler et al. 2008). Together, the methodologies support decision-making on a long-term basis and ensure the sustainability of investments from multiple perspectives.

Risk management is the third-leading reason why companies should utilize LCA studies. For example, legislation can change due to increasing awareness about the issues that threaten sustainability. Also, competitors may adopt aggressive sustainability strategies to utilize the growing interest from customers to support sustainable

development. To prepare oneself for environmental risks, the LCA results need to be examined in combination with the LCCA information.

The Role of Life Cycle Assessment in Fulfilling a Company's Sustainability Strategy

Nearly all companies are required to comply with some form of legal requirements related to sustainability. However, not all companies occupy a position within the product chain from which they have an opportunity to impact the decisions of other actors. In such a case, it may be sufficient to follow changes in legislation and emerging drivers.

Some companies need to meet stakeholders' expectations regarding environmental or sustainable responsibility. However, others are not under such pressure, even from their B2B customers. This could be because they have a relatively small footprint at that stage of the life cycle or because they operate in markets that have yet to emphasize these aspects. It is essential to bear in mind that the situation may change in the future when raising awareness and/or improvements achieved in other parts of the production chain may put smaller actors under the spotlight.

In the opposite case, in which a company is approached with inquiries about their responsibility, it should be in a position to provide data pertaining to activities, for example, its carbon or water footprint. Also, companies that are positioned closer to the final user within the life cycle may need data for environmental product declarations as part of certification processes.

A sustainability risk is an uncertain social or environmental event or condition that can cause a significant negative impact on the company (WBCSD 2017). By being prepared to provide responses and data in response to stakeholder inquiries, companies are protected against any risks that are derived from sustainability issues. However, companies may also pursue further advantages by assisting their suppliers and customers to meet their respective sustainability goals. Sometimes, this may entail entering into strategic partnerships with other companies to discover an ultimate solution. LCAs and LCCAs may be needed to identify the costs and benefits of

such undertakings from the perspectives of all parties.

However, in most cases, small steps toward sustainability are not enough; instead, radical changes to current practices are needed. Therefore, the real forerunners from the sustainability point of view are companies that have engaged in the development of products and services that can meet the sustainability demands of the future. LCAs and LCCAs represent useful tools in this process.

Summary

The LCA is a standardized method for assessing the potential environmental impacts of products, product systems, and services. As such, it can be used to facilitate various decision-making situations. Today, the LCA plays a significant role in helping organizations and researchers to recognize and implement methods of tackling sustainability challenges and ensure that any sustainability changes that are suggested make sense from the resource use point of view. The LCA methodology also forms the basis for the two internationally standardized LCA-based footprints (carbon footprint and water footprint). In addition, current ongoing product environmental footprint guidelines for development follow the principles of LCA. The purpose of the LCA is to search for the most beneficial environmental impact reduction points within the production chain, while the use of footprint measurements enables different production systems to be compared.

The approach aims to prevent environmental problems shifting from one life cycle stage to others. The methodology consists of four main steps: goal and scope definition, life cycle inventory, life cycle impact assessment, and interpretation. By following these phases, practitioners can ensure that the study is outlined, conducted, and verified in a way that produces reliable and valid scientific results. The guidelines for completing the different LCA phases are described in the ISO 14040 and ISO 14044 standards. If the LCA is used for comparative assertions and to be made

publicly available, the study will need to be performed according to stronger regulations and the results verified by a critical review before publication.

[Life cycle analysis](#)

Description

Life cycle assessment (LCA) is a technique for assessing the sustainability of a product (either

goods or service) over its entire life cycle from cradle to grave (ISO 2006). A product's life cycle consists of consecutive and interlinked stages of a product system, including acquisition of raw materials, design, production, transportation/delivery, use, end-of-life treatment, and final disposal. Broadly, there are two complementary branches of LCA. Environmental life cycle assessment (ELCA) assesses the impacts on human and ecosystems (Heijungs et al. 1992), while social life cycle assessment (SLCA) evaluates the social impacts through a product's entire life cycle (Andrews 2009).

LCA applies life cycle thinking (LCT) that goes beyond the traditional scope of the production site and manufacturing processes by analyzing the environmental, social, and economic impacts of a product during its entire life cycle. LCA findings offer valuable information that could improve target audience's understanding of the broad impacts of production and consumption decisions and address the shared concerns about the state and sustainability of our society. For producers, LCA could identify opportunities to improve the environmental and social impacts of products at various points in their life cycle and avoid local improvements in design and production that merely shift impacts. For value chain actors (from suppliers, producers, traders, to consumers), LCA facilitates their choices by providing relevant indicators of sustainability performance to be used in marketing and communication, eco-labeling scheme, and environmental product declaration. For decision- and policy-makers, LCA supplies critical input for strategic planning, priority setting, and public policy toward the goal of responsible production and consumption.

Life Cycle Thinking as the Guiding Principle

Life cycle thinking (LCT) guides the development and implementation of life cycle assessment (LCA) methods. LCT is a new way of thinking that goes beyond a product's design and production stage but considers the economic,

Life Cycle Assessment: Products and Services, Fig. 1 Cradle to grave: five stages in the life cycle of a product (illustration developed according to the Life Cycle Initiative 2019)

environmental, and social consequences of a product or process over its entire life from “cradle” (i.e., extraction of raw materials) to “grave” (i.e., disposal), as illustrated in Fig. 1.

At the core of LCT is the respect for planetary limits and responsibility for system-wide impacts of our actions. The publication of *Limits to Growth* (Meadows et al. 1972) as well as the energy crisis in the 1970s focused global awareness on the challenges associated with industrial development on a planet with finite supply of resources. One of the first limitations that industrial development encountered is the environment’s ability in pollution absorption (Meadows et al. 1992). LCA constitutes a proactive approach to understanding and managing such damages to the socio- and ecosystems.

Life cycle thinking leads to a fundamental shift in the decision-making in many organizations. Traditionally, an organization is only concerned with activities within its own boundary. A manufacturing firm would monitor the design and production stage and work toward reducing material, water, and energy use of their products directly under its own control (indicated by the thick-outlined textbox in Fig. 1). This inward-looking reduction strategy however could result in worse sustainability performance over the entire life cycle of a product if the reduction at the production stage causes higher material and energy use in other stages. For example, changing to recycled glass bottle packaging at a brewing company requires higher use of water and energy to collect, transport, sort, clean, crush, heat, and reform the recycled glass. The total impact of all these activities must be considered to evaluate the packaging decision properly and reduce the risk of local optimization. According to Remmen (2007), an organization that has adopted LCT will need to:

- Establish controls as appropriate to ensure that its environmental requirements are addressed in the design and development process for the product as well as in each stage of its life cycle
- Collect data (stories and other qualitative data) on the social performance of production and consumption; analyze associated impacts on the workers, the local communities, the consumer, the society, and other value chain actors
- Determine its requirement(s) for the procurement of products and services as appropriate
- Communicate its relevant sustainability requirement(s) to external providers, including contractors
- Consider the need to provide information about potential significant impacts associated with the transportation or delivery, use, end-of-life treatment, and final disposal of its products

LCT also has far-reaching implications for interactions among organizations. A holistic, systematic, and rigorous assessment of the life cycle impacts requires all organizations involved to be open and cooperative. In addition to sharing information, organizations need to collaborate on developing and implementing reduction strategies that improve system-wide performance.

A Brief History of Life Cycle Assessment

After early environmental life cycle assessment (ELCA) reports appeared in the 1970s and 1980s, major efforts in the diffusion and standardization of ELCA occurred in the 1990s. The University of Leiden published the first comprehensive ELCA guide (Heijungs et al. 1992), partly as a response to the call for accelerated product policy measurement by the Netherlands National Environmental Policy Plan Plus (NEPP-plus).

The guide argued that a good product policy can be implemented through ELCA for the benefits of both the producers and the consumers by considering the entire life cycle of a product and assessing it in relation to all aspects of the environment. The editors of the guide shared their perspective on the relationship between ELCA and sustainable development in the Foreword: “the outcome of an environmental life cycle assessment can never legitimize our consumption. There are no environmentally-friendly products, some products however are more environmentally-friendly than others” (Heijungs et al. 1992, p.v).

In 1993, the Society of Environmental Toxicology and Chemistry (SETAC), the leading international organization for the coordination of the methodological development of LCA, held an expert workshop in Portugal and established a *Code of Practice* which included the definition of a technical framework for LCA consisting of components and a uniform terminology.

In 1996, the International Journal of Life Cycle Assessment was created. This is the first journal devoted entirely to life cycle assessment and closely related methods. The journal’s major contributors and audience include scientists developing LCA and life cycle management (LCM); LCA and LCM practitioners; managers concerned with environmental aspects of products; governmental environmental agencies responsible for product quality; scientific and industrial societies involved in LCA development; as well as ecological institutions and bodies (IJLCA n.d.).

From 1997 to 2006, the International Organization for Standardization (ISO) published a series of ISO 14000 standards on ELCA. The ISO continues to update and develop international standards related to ELCA and SLA (Finkbeiner et al. 2006).

Since 2002, the Life Cycle Initiative, a collaboration between the United Nations Environment Program (UNEP) and the Society of Environmental Toxicology and Chemistry (SETAC), has been a global driving force to develop a science-based, consensus-building process for supporting decisions and policies toward the shared vision of sustainability as a public good. The Life Cycle

Initiative delivers authoritative opinion on sound tools and approaches by engaging its multi-stakeholder partnership (including governments, businesses, scientific and civil society organizations). For example, the UNEP/SETAC Life Cycle Initiative Social LCA Project group started their work on methodological sheets in 2005. Detailed guidelines on how to collect, analyze, and distribute SLCA studies are being actively developed (Andrews 2009).

The Life Cycle Assessment (LCA) Method

Before starting an LCA, the practitioner must be aware of the significant amount of time needed to collect and prepare the data. There are also other practical limitations. The accuracy of LCA studies may be limited by the accessibility, availability, and quality of relevant data. Data acquired could have gaps, require aggregation, or are site-specific. The results of an LCA are susceptible to a number of subjective factors, such as system boundary setting, selection of data sources, impact assessment method, and social impact categories. Therefore it is essential to adopt a critical approach and carefully check the assumptions and choices as well as their implications throughout an LCA. These choices and assumptions should be explicitly stated for reasons of transparency. Generally, the information developed in an LCA study should be used as part of a much more comprehensive decision process or used to understand the broad trade-offs. Comparing results of different LCA studies is only possible if the assumptions and context of each study are the same.

An LCA study follows four interdependent phases: goal and scope definition, inventory analysis, impact assessment, and interpretation (ISO 2006) (see Fig. 2).

Environmental Life Cycle Assessment (ELCA) Method

ELCA is a technique that assesses the environmental impacts associated with a product by compiling an inventory of relevant inputs and outputs

Life Cycle Assessment: Products and Services, Fig. 2 Four major interconnected phases in the process of an LCA study (illustration developed according to ISO 14040)

of a product system throughout its life cycle, evaluating the potential environmental impacts associated with those inputs and outputs, and interpreting the results of the inventory analysis and impact assessment phases in relation to the objectives of the study.

Goal and Scope Definition

An ELCA study begins by explicitly identifying the context of the study and explaining the *how* and *to whom* the study should be communicated (ISO 2006). To this end, this phase provides technical details that ensure consistent performance and intended application of the ELCA study. One of the most fundamental technical details provided in the goal and scope definition phase of an ELCA is the definition of a **functional unit**, which is a quantitative description of the product system in terms of the function provided. For example, the functional unit of an LED bulb could be defined as “lighting 1 square meter with 3,000 lux for 10,000 hours with daylight spectrum at 5000K.” This precise definition of the product function not only sets up the **system boundary** for delineating which processes to be included in the analysis but also serves as a comparative unit between products. A poor definition of the functional unit can lead to comparison of alternatives that are not actually achieving the same function and thus jeopardize the validity and relevance of the study. This phase also specifies any **assumptions and limitations**, as well as **allocation methods** if multiple products or functions share the same processes (Finkbeiner et al. 2006).

Life Cycle Inventory (LCI) Analysis

In life cycle inventory (LCI) analysis, the practitioner examines all the data on **environmental inputs and outputs** associated with a product or

service and uses them to develop a flow model of the technical system. The data must be related to the functional unit defined in the goal and scope definition phase. Inventory flows include inputs of water, energy, and raw materials and releases to air, land, and water. In addition, it is important to address data quality requirements such as the precision and completeness of the data, consistency and reproducibility of the methods used throughout the process, sources of the data and their representativeness, uncertainty of the information, etc. LCI contributes to forming a complete picture of the matter, energy, and substance flows that cross the system boundary.

Life Cycle Impact Assessment (LCIA)

Life cycle impact assessment phase aims to connect the LCI results to their potential impacts. Major LCIA activities include (1) classification, assigning inventory data to impact categories by evaluating them based on the priorities of the target audience; (2) characterization, modeling the inventory data by translating them into mid-point impact categories; and (3) calculation – using appropriate indicators to show the amount of damages to **human health, natural environment, natural resources, and man-made environment** (Joliet et al. 2004). The most important choice the practitioner has to make is the desired level of integration of the results. This usually depends on how she would like to address the audience and the ability of the audience to understand detailed results. Figure 3 illustrates the LCIA process of an ELCA.

LCIA frameworks are being actively developed by the Life Cycle Initiative. Taking a worldwide perspective, the UNEP/SETAC Life Cycle Initiative aims to outline a more precise and broadly agreed description of main framework

elements, thus providing a common basis for the further development of mutually consistent impact assessment methods for both developing and developed countries. Ongoing development efforts include a global process that establishes consensus around the appropriate indicators and characterization factors for LCIA in various areas (Jolliet et al. 2014).

Interpretation

Throughout the LCA phases, the results should be regularly interpreted. This allows various assumptions and subjective choices at each stage to be checked and ensures that the conclusions about the impacts are well-substantiated. Regular interpretation also enhances decision-making because the stage that generates the greatest impacts is likely to have the greatest potential for impact reduction. The ISO 14044 standard describes a number of methodological and study limitation checks to test whether conclusions are adequately supported by the data and by the procedures used (Finkbeiner et al. 2006). By following the standard, the practitioner can share the results and improvement decisions with the world without suffering from common pitfalls.

Social Life Cycle Assessment (SLCA) Method

Social life cycle assessment studies follow similar phases but differ in some aspects due to their unique focus on the social and social-economic influences of the products in different phases on different stakeholder groups. There is a strong emphasis on business procedures through the life cycle of a particular product. This interest is associated with the idea that the product is considered accountable for a range of negative and positive impacts on different groups of stakeholders (Andrews 2009).

The mix of quantitative, qualitative, and semi-quantitative data is unique to SLCA (Andrews 2009). The activity variables such as the number of working hours for estimating the share of each unit process in the product system are more often collected and used in SLCA. The subjective data, such as stories and other qualitative data from the stakeholders, could sometimes be more appropriate information to use in SLCA. Bypassing subjective data in favor of more “objective” data could introduce greater uncertainty. In addition, SLCA will need to provide information on the level of engagement of stakeholders. Methodological transparency

Life Cycle Assessment: Products and Services,

Fig. 3 Life cycle impact assessment framework for ELCA (illustration developed according to Jolliet et al. 2004)

Life Cycle Assessment: Products and Services, Fig. 4 SLCA impact analysis framework (illustration based on Andrews 2009)

and frequent assumption and situation checks are particularly important in SLCA (Norris et al. 2013).

During the **goal and scope definition** phase, SLCA requires that practitioners consider the social impacts of the product use phase and function (UNEP 2009). SLCA encourages that external stakeholders be involved in providing input on impacts. During **inventory analysis**, a substantial task is to identify the most significant group of stakeholders that is affected by a product or a business. The key criterion to select stakeholder groups and place them into various stages is their relevance to the context of each stage. SLCA may require site-specific **LCIA** in some cases and may also need information about “political” attributes, such as country and its laws. There are 31 sub-categories in the methodological sheets published by the UNEP/SETAC Life Cycle Initiative (Norris et al. 2013). The subcategories are classified both by stakeholder categories and impact categories. Justification needs to be presented when a subcategory is not included. The impact analysis phase in SLCA follows the steps outlined in Fig. 4. It is important to note the stakeholder-based characterization process. The social performance results could be better or worse than the reference points, or thresholds, that the site is compared to. Aggregating the results in very specific cases is possible but only when meaningful.

Summary

Pressure on our environment and society as a result of the production and consumption by the human systems remains a primary challenge of our time. The LCA technique strives to maintain a balance between scientific rigor and practicality to provide a systematic approach that monitors, quantifies, and manages man-made impacts. In keeping their relevance and comparability, the LCA studies aid the achievement of the sustainable development goals at the global level, one product at a time.

LCM; Value chain management

Description

Life cycle thinking is an idea, a mental approach, and a philosophy of behavior which means going beyond the traditional focus on production sites, and taking care of environmental, economic, and social impacts of products along their entire life cycle, with the aim of increasing sustainability. A life cycle approach can be used in different phases and by different actors, such as product designers, innovators, producers, governmental authorities, and consumers, to make better choices.

Life cycle management (LCM) is the organizational dimension of life cycle approach (Andrews et al. 2009). It means the use of life cycle approach for managing, taking decisions, and implementing strategies, in order to make production and consumption more sustainable. It can use numerous analytical (such as LCA, LCC, and carbon footprint), procedural, monitoring, communication, and reporting tools, which give a specific perspective regarding the products' life cycle impacts and help to identify the areas of intervention. LCM can be applicable to primary and secondary sectors as well as any types of organizations such as public administrations.

Introduction

The life cycle approach finds its origin back in the 1960s, since when some researchers started to analyze the problem of natural resources consumption and understood that the only possible and effective way to study complex systems was to take into account the whole flow of materials

from their extraction, through their transformation and consumption, to end into the waste phase: the so-called cradle to grave approach (Alting and Jorgensen 1993). A further improvement has been the rise of consciousness about the necessity to close the cycles, in order to decrease the pressure on natural resources and reduce also the environmental impact. So, from the cradle to grave approach, we now talk about the cradle to cradle (C2C) approach. Cradle to Cradle® is a design concept inspired by nature, in which products are created according to the principles of an ideal circular economy. It is about eco-effectiveness and goes beyond conventional sustainability tools and approaches, and its implementation creates equal economic, social, and ecological benefits (EPEA GmbH, 2019). Resource efficiency (see Ecoefficiency) is then the basis for decoupling economic growth from resource use and environmental degradation and also meeting, at the same time, human beings and well-being. The whole value chain needs to be considered to improve the management of resource stocks, reduce inputs, optimize production processes, improve logistics, change consumption patterns, and minimize waste. To reach this goal, new products and services also need to be developed (EU, 2019). Producers, designers, raw material and component suppliers, retailers, consumers, transporters, waste managers, recyclers, public authorities, regulators, and financial organizations are all involved in the change.

To move life cycle approach from theory to reality, numerous tools have been developed during the past two decades.

LCM and LC Tools

The majority of impacts (environmental, social) of products do not occur where they are produced, but rather upstream and downstream in the value chain (see Value Chain Management), out of the production sites and outside the companies' direct control. In order to put more light on the hidden or delayed impacts and to avoid burden shifting, a number of assessment instruments have been developed in recent years to provide more precise predictions of various noneconomic

consequences of decision-making, either at business level or at administration level (Balkau et al. 2017).

Among these instruments, LCA (see LCA) is the key methodology to assess the environmental impact along the whole life cycle of products (see product life cycle) and services and for improving resource efficiency (European Commission 2010). LCA also provides information about at which stages of the product's life cycle the environmental impacts are more relevant.

Starting from Environmental LCA methodology (E-LCA or just LCA) and based on LC thinking (see life cycle thinking), many other assessment tools have been developed, such as:

- MFA (Material Flow Analysis)
- SFA (Substance Flow Analysis)
- RA (Risk Assessment)
- IOA (Input-Output Analysis)
- EF (Ecological Footprint)
- CF (Carbon Footprint)
- WF (Water Footprint)
- LCC (Life Cycle Costing)
- S-LCA (Social LCA)
- O-LCA (Organizational LCA)

Among them, S-LCA and O-LCA are the latest ones which have been developed.

LCA methodology, until recently, has been used to assess the real and potential impacts that a product has just on the environment, in terms of pollution and resources depletion along its life cycle; but life cycles of products involve also economic flows and have effects on all the value chain actors (workers, local communities, consumers, the society...). For this reason, the new S-LCA tool gives information about social externalities and assesses social impacts (positive or negative) of products along the LC. S-LCA technique promotes improvement of social conditions throughout the life cycle of a product (Andrews et al. 2009). It complements LCA and can be applied alone or in combination with LCA.

The benefits and the usefulness of life cycle approach are not restricted to the assessment of single products and can easily be demonstrated also when applied to organizations, to assess their performance regarding the environment.

The environmental impact assessment of an organization is definitely more complex than that of a single product for many reasons: One organization can produce different products, be involved in different sectors, have different production sites, manage different activities, involve different business divisions and departments, work with many suppliers, and purchase many different raw materials (Blanco et al. 2015). So, in order to help organizations to understand the environmental impact of their product portfolio along the whole value chain, the O-LCA methodology has been developed.

O-LCA is a multi-impact approach, which can be used by organizations to support them in reaching analytical, managerial, and societal goals, through the identification of hotspots for decision-making.

The ultimate goal of sustainable development is in fact the well-being and the quality of life, considering environmental, economic, and social dimensions.

The output of LC methodologies consists usually of technical information and data, but in order to be useful to managers and decision makers, these need to be accompanied by applicable information on economic aspects and policy options, especially when alternatives have to be compared. Any systematic management approach needs good data and well-defined objectives.

While the application of life cycle approach to product design is increasing fast, its contribution to programmatic development is still small. In part, this is due to lack of understanding by non-technical actors, such as public administrators and project managers, of its potential utility. In other words, it is necessary to move from the assessment of impacts of goods and services, to a systematic management of reduction of those impacts. Life cycle management can be considered as the application of life cycle thinking in modern business practice, and LCA is just one possible tool useful to design a LC management strategy. LCM is not a single tool, but rather a framework to analyze and then manage the performance of goods and services in terms of sustainability and support more sustainable value chains.

A general current trend in companies and in governmental policies is toward Integrated Management Systems which can take into account at the same time the environmental, social, and economic dimensions of their activities and decisions. In this context, LCM is evolving through the development of numerous LC tools, useful to assess, analyze, integrate, communicate, and manage.

Conclusions

A big challenge for implementing LCM is first of all to identify, in the entire life cycle of products, the main actors who manage different stages along the life cycle and the stakeholders involved, who are usually multiple, independent part-players, and subsequently bring them together for adopting the most efficient models of management. This will build up connections between the supply chain and the value chain. In addition, defining a LCM strategy may affect most of the departments and functions of an organization.

Many organizations which have adopted LCM have seen several improvements in: their image, stakeholder relations, and shareholder value, as well as awareness of coming changes to their regulatory contexts (UNEP/SETAC 2009). In order to get these advantages, an important step in LCM is the communication of LC information outside the organization boundaries, and for this aim many tools have been created and adopted; many of them have also been standardized. Some of them include green reporting, sustainability reports, certification systems, environmental product declarations, ecolabels, product environmental performance indicators, green public procurement guidelines, company codes, or manuals of conduct. Each organization has to select the most appropriate and useful tools.

In conclusion, LCM is a strategic managerial approach which can be adapted to any specific situation and context by the choice of the most suitable LC tools to each organization, with the aim of increasing its environmental performances as well as the social ones, taking into account the entire value chain connected with their own

products and activities. Key drivers for implementing LCM are the corporate strategy, specific requirements from the finance sector or from the market and regulations.

Summary

Life cycle management can be defined in different ways, one of which is: “LCM is a life business management approach that can be used by all types of organizations to improve their products/services and thus the sustainability performance of the companies, with the aim of ensure more sustainable value chains” (UNEP/SETAC 2009). LCM is useful for targeting, organizing, analyzing, and managing information and activities for improving sustainability along the life cycle (Remmen et al. 2007). LCM is voluntary and can be adapted and gradually introduced in any organization, including SMEs, integrating it in the core operations of business. LCM is usually better implemented through a step-by-step process.

Life cycle application; Life cycle theory

Definition/Description

Life cycle management (LCM), as initially defined by Hammer (1981), is a tool focusing simultaneously on three major functional aspects: planning, monitoring, and control. The LCM tool is designed to supply a complete overview whether of some project or product or even a whole company. Thus, this deals with every aspect of organizations from their very launch to their final closure, involving all the real and virtual

costs arising from the project (Hammer 1981). These costs must include those related with planning (design), development, production (operation and maintenance), distribution and those associated with the demise of the product, service, or entity at the end of its anticipated useful life span. Hammer (1981) divides life cycle management into six stages: mission analysis and project initiation, concept development, definition and design, system development, development and operation, and, lastly, transition or termination.

Background

The life cycle of a company or business was first studied by Haire (1959), who made an analogy between business life and biological life as the development of the former aligned with the growth curve in biology. Gardner (1965) also argued that the life cycle of a company was comparable to that of humans or other living beings. Studies then began to emerge analyzing company stages and the causes of movement between them, including premises for survival. This life cycle approach was then applied to specific products and services and also to intangibles within a company. Thus, the LCM concept began emerging.

The typical life cycle categories generally consist of the birth, growth, mature, and decline stages. The main goal of LCM is to maximize the value of any tangible or intangible asset taking into consideration its expected market life. Costs need reducing and the environmental and socio-economic impacts on economy must be carefully addressed. Accordingly, LCM may be viewed as an “integrated framework of concepts and techniques to address the environmental, economic, technological and social aspects of products, services and organizations” (Hunkeler et al. 2004). The standard life cycle framework of phases for asset systems includes the conceptual design, the preliminary design, detailed design and development, production and/or construction, utilization and support, and the retirement and disposal stage coinciding with the demise of the asset (Labuschagne and Brent 2005). Life cycle management (LCM) provides an adequate framework

for analyzing and managing the sustainability of goods and services and improving the environmental, social, and economic performance and thus contributing to life cycle thinking (LCT) (Ortiz-R et al. 2014).

LCM foresees the application of life cycle thinking to businesses aiming to manage the total life cycle of an asset or service as a means to more sustainable consumption and production. Life cycle management encourages companies to integrate the cost of externalities into their products and services, that is, those impacts beyond the boundaries of financial transactions. Accordingly, companies have to shape and condition the material, energy, and financial flows across the full life cycle of their product offerings (Swarr 2006). However, not all externalities are included in pricing processes, which might be perceived as a potential market gap for green products and services (Swarr 2006). Companies will then follow demand by producing green and natural products with lesser environmental and health impacts. This ultimately leads to reduced government regulation for green products and services because companies are already anticipating trends and offering products with high environmental and health-related features and thereby offsetting the need for government intervention. Swarr (2006) puts forward the example of indoor environmental quality products that reach beyond energy savings to reduce respiratory-related diseases (allergy, asthma) and thus government costs on treating those illnesses also fell. Accordingly, two strengths emerge as launching a new product or green service can indirectly appear as mitigating for a past company illegality that might still cause liabilities and litigation. A company that defends the provision of a healthier version of its own product indirectly accepts that the earlier version was not as health compliant and thus potentially liable to litigation. On the other hand, governments tend to pass on the cost of externalities to industry rather than increasing general forms of taxation (Swarr 2006).

LCM thus allows companies to expand their horizons by enabling the identification of new areas for improving and promoting products and services (Kurczewski 2013). Consequently, life

cycle thinking (LCT) has emerged as an approach returning comprehensive analysis of the environmental impacts, economic costs, and social consequences experienced during the life cycle of products. Methods to address LCM have included life cycle assessment (LCA), life cycle costing (LCC), and social life cycle assessment (SLCA), well known both in academia and among large companies. The environmental impact of life cycle techniques (LCTs) (Kurczewski 2013), such as energy consumption, reducing the waste requiring disposal, cutting construction particulate emissions, noise and gas emissions whether in Industry, Construction, Trade, Finance and Services sectors are facets at the core of LCM. Life cycle thinking, life cycle assessment, life cycle management, and life cycle costing are interrelated concepts with all focused on sustainable product chains. Life cycle thinking (LCT) constitutes a term that pursues explanations and understanding of human and organizational factors whereas LCM focuses on the tools and factors vital for success. Life cycle assessment (LCA) tool serves to study sustainable products and their social, economic, and ecological impacts through measuring environmental performance; the consumption of natural inputs and the emissions returning to nature through production processes. LCA thus considers environmental impacts throughout the life cycle (Ortiz-R et al. 2014) with its methodology following the ISO/TS 14072:2014 standards (International Standardization Organization 2014) in order to deliver a valuation of the ecological performance of a product or service throughout its life cycle; from raw material, production or processing, utilization, and through its subsequent disposal. Therefore, LCA evolves over four steps: defining the goal and scope, inventory analysis, impact assessment, and interpretation (Ortiz-R et al. 2014). Gundes (2016) advocates the life cycle costing (LCC) methodology and its main goal of achieving investment efficiency by incorporating economic factors into the assessment of sustainability. LCC acts through interrelating alternative design strategies in keeping with their respective initial, maintenance, and operational costs calculated over specified periods of time.

Ristimäki and Junnila (2015) defend that sustainable value is created only when considering the development of the economic, ecological, and social concepts throughout the entire life cycle, which can be performed using LCM to continuously improve and boost the sustainability performance. Ristimäki and Junnila (2015) defend a holistic life cycle approach as capable of generating both more coherent urban development and potential positive impacts on sustainability. The framework above establishes the foundations of LCM.

LCM Tools

Various examples of commonly applied LCM tools and methods include life cycle sustainability assessment (LCSA), life cycle costing (LCC), environmental life cycle assessment (LCA), and social life cycle assessment (SLCA) as stated by Kloepffer (2008).

Among the methods and tools with LCM applications are: LCA, product flow analysis, life cycle costing (LCC), environmental management systems, ecolabeling and environmental product declarations, product policies, design for environment tools, footprint analysis, and key performance indicators as detailed by Balkau and Sonnemann (2010) and summarized by Nilsson-Lindén et al. (2018). LCM strives to deploy an integrated approach to sustainability in keeping with the respective product life cycle.

Labuschagne and Brent (2005) defend sustainable development with facets such as social equity, economic efficiency, and environmental performance needing to be incorporated into both real-time project management methodologies for appraisals and decision-making processes. Furthermore, achieving this inherently needs understanding and integrating LCM. Labuschagne and Brent (2005) propose a framework specifically for sustainability performance evaluation consisting of a corporate responsibility strategy split into operational and social initiatives. These then subdivide into economic sustainability, environmental sustainability, and social sustainability. In turn, economic sustainability includes economic performance, financial strength, and potential financial benefits.

Environmental sustainability spans the consumption of air, water, land, and mineral and energy resources. Social sustainability respectively comprises of internal human resources, external populations, stakeholder participation, and the macro social performance.

Environmental LCM provides a technique for applying a holistic perspective within the scope of which corporate environmental concerns span the entire product chain with the goal of reducing the total environmental impact. Corporate environmental management deploying a life cycle perspective throughout the value chain is commonly referred to as environmental life cycle management (ELCM) (Fava 1997; De Leeuw 2006; Nilsson-Lindén et al. 2018).

Life cycle analysis (LCA), similar to life cycle assessment (LCA), represents a decision-making support tool with the goal of evaluating environmental factors. LCA thus seeks to evaluate the potential environmental impacts of a product or a process across its entire life cycle (Gundes 2016).

The International Organization for Standardization (ISO) standard 14,040 is the international standard for LCA. This ISO describes life cycle assessment (LCA) as the “compilation and evaluation of the inputs, outputs and the potential environmental impacts of a product system throughout its life cycle” (ISO 14040 2006). The LCA methodology put forward in the ISO contains various steps such as defining goals and targets, inventory analysis, impact assessment, and interpretation (Gundes 2016). LCC and LCA both address life cycle thinking but are nevertheless dissimilar in purpose, scope and methodology. Combining or integrating the existing tools provides the first step towards more inclusive sustainability assessment: Life cycle sustainability analysis (LCSA) = LCC + LCA + SLCA (social life cycle analysis, or the impacts on stakeholders) (Gundes 2016).

Requirements for Applying LCM

Nilsson-Lindén et al. (2018) defend that the application of LCM proves problematic as its research fails to address the complexity of organizing LCM in practice. The authors reflect on the means of

implementing life cycle-based thinking in companies. The factors driving LCM success, according to the review by Nilsson-Lindén et al. (2018), are: (1) top management backing (avoiding resistance and disruption), (2) communication and collaboration (exchanging ideas across the organization) among all stakeholders and personnel, (3) integration across functions (the participation and collaboration of employees in the most organizational functions and levels are vital to LCM success), (4) applying LCM practices as daily routines, (5) LCM does not embody an additional strategy but instead aligns with the existing business strategy, (6) knowledge about LCM (time for education and training), (7) the holistic environmental approach, and (8) ensuring the collaboration of all players in the product chain.

LCM Applications

Life cycle management has been applied to pharmaceuticals (Modi 2017), agriculture (Ortiz-R et al. 2014; Ruviaro et al. 2012), real estate (Ristimäki and Junnila 2015), electronic systems (Hammer 1981), the health sector (Daidoji et al. 2013), corporate life cycles and their cyclical movements (Pai et al. 2014; Reis and Augusto 2015; Habib and Hasan 2018), knowledge management (Evans and Ali 2013), activity based costing (ABC) (Kallunki and Silvola 2008), the construction industry (Gundes 2016), in inventory management (Elsayed and Wahba 2016), the strategic planning methodology (Kniazieva et al. 2018), financial reporting Habib and Hasan (2018), and to SMEs (Kurczewski 2013).

In turn, organizational life cycle (OLC) theory has been applied to the organizational behavior literature with OLC stages deployed to foresee the performance of organizations (Kimberly et al. 1980; Miller and Friesen 1984). The authors found that company strategies, structures, and decision-making processes display distinct characteristics according to the respective life cycle stage. These life cycle stages span birth, growth, maturity, decline, and revival. Birth characterized by young and innovating companies seeking to strengthen their position in niche markets, growth featuring high turnover growth rates and several organizational departments, maturity displaying

stability and efficiency, decreases in innovation and with the appearance of a more bureaucratic structure, with revival in turn characterized by product variation with innovations recreating the product while the declining phase encapsulates stagnation and old fashion product lines.

Management science adopted the LCM concept in order to improve cost-effective choices about the installation and operation of electronic systems (Hammer 1981). Modi (2017) reinforces the role of LCM within the framework of maximizing asset values (pharmaceuticals) during their lifespans. In this case, implementing an LCM plan begins at product launch or subsequently when a drug demonstrates the potential for returns from additional investment while also encompassing efforts to market drugs following patent protection expiry and the corresponding market decline. Life cycle approaches may also involve new formulations, new routes of delivery, new indications or expansions in the population for prescription or the development of combination products. Life cycle management may also return opportunities to improve upon the current product through enhanced efficacy or reduced side effects, better tolerability or better prescriber, or patient acceptance and expanding the therapeutic market for the product (Modi 2017). Daidoji et al. (2013) defend that LCM maximizes the value of existing drugs (pharmaceuticals) and extends the product life indicating that the most common pharmaceutical LCM strategies include various techniques such as new indications, new formulations, new combinations, authorized generic, over-the-counter drug switches, and pricing strategies.

Pai et al. (2014), based on corporate life cycle theory and risk management, applied a pre-warning of risks to avoid financial stress during each life cycle stage and thus increasing the probability of corporate survival. Corporate life cycle theory divides company lifespans into several stages most commonly totaling four – birth, growth, maturity, and decline – in accordance with four measurements: rate of sales growth, capital expenditure, dividend pay-out ratio, and firm age (Black 1998; Pai et al. 2014).

Elsayed and Wahba (2016) analyze inventory management in keeping with the life cycle stages

and demonstrate how the inventory to sales ratio shapes company performance levels negatively in the initial growth stage and the maturity stage but drives a positive impact on performance in either the rapid growth stage or the revival stage.

The application of life cycle models to strategic planning allows for the forecasting of sales able to assist in planning production, determining the best strategies for different stages of development; calculating the sequence of stages in company development while also providing an equilibrium between organizational features and the external environment, which furthermore influences the process of organizational development (Kniazieva et al. 2018). For this purpose, Kniazieva et al. (2018) point to the need to observe the interconnections among life cycles across all levels: industry, technology, enterprise, and product. The tools of the life cycle theory strategic planning methodology include perceiving the need to consider factors of time and uncertainty in strategic planning; setting tasks within conditions of uncertainty; real-time adjustment; and evaluating the effectiveness of strategic decisions (Kniazieva et al. 2018).

Phan et al. (2014) study the appropriateness of deploying activity based management (management accounting practices) (ABC) practices across different organizational Life cycle stages given that they find that the maturity and revival businesses stages apply each level of activity based management more often than entities going through the birth, growth, and decline stages. ABC generated information improves the accuracy of product/service costs to a greater extent than the traditional cost approach. The association between the OLC stages and recourse to ABM cost procedures enables management awareness of their business unit's stage of development and its respective needs whenever minimizing costing systems Phan et al. (2014).

Regarding the application of LCM to knowledge management, Evans and Ali (2013) propose a holistic view incorporating three different perspectives: knowledge assets, life cycle stages, and enabling initiatives and technologies. Knowledge assets constitute the value-added intellectual

resource in the form of the stocks of knowledge, whether formalized or tacit, that employees tactically apply to problem solving through recourse only to memory.

Habib and Hasan (2018) state that managerial efficiencies, flexibility, and company resources determine the transitions through the corporate life cycle. The corporate life cycle furthermore influences the financial reporting of companies, the extent of their disclosures, the terms for corporate investment, financing and as well as decisions over payouts and dividends. Additionally, the life cycle frames corporate governance and socially responsible behavior (Habib and Hasan 2018). As regards financial reporting, the relevance of accounting information differs according to the stage in the firm life cycle. In early stages, there are fewer invested assets resulting in lower or negative operating cash flows. Mature firms hold larger investment portfolios, with greater access to financing thus requiring improvements to the quality of information and with corporate disclosures correspondingly increasing. Firms similarly engage in different levels of tax planning activities across their life cycle stages that also shape the choice of management control tools. The life cycle furthermore impacts on board structures, levels of management compensation, and corporate social responsibility (Habib and Hasan 2018). The determinants of firm life cycle dynamics interrelate with organizational capital, management practices, corporate structure, flexibility, and venture capital participation.

Summary

Considering the typical life cycle stages of a tangible or intangible asset, company process, system, LCM and its related tools provides a holistic approach for dealing with all of the externalities and cost efficiencies incurred over the life span of any asset. This approach thus necessarily includes environmental, economic, social, financial, strategic, and administrative issues that require holistic assessment and management. As this applies to human beings, LCM is suitable for adaptation to every branch of industry. Despite the already

extensive research, more practical examples are needed to reinforce its applications to other fields.

Definition

Life cycle sustainability assessment (LCSA) is a systematic and comprehensive evaluation approach that assesses the full range of environmental, social, and economic impacts of a product, system, or process throughout its entire life cycle, from raw material extraction to end-of-life disposal. The purpose of LCSA is to identify and understand the trade-offs and potential sustainability challenges associated with the product, system, or process and to inform decisions that can enhance its sustainability. LCSA considers multiple sustainability criteria, including environmental impacts, such as greenhouse gas emissions, resource depletion, pollution, and waste generation; social impacts, such as labor practices, human rights, health, and safety; and community engagement and economic impacts, such as resource use, energy efficiency, cost, and economic viability. LCSA can be used by companies, governments, and other organizations to assess the sustainability of existing products, systems, and processes; identify opportunities for improvement; develop more sustainable products, systems, and processes; demonstrate sustainability leadership and meet stakeholder expectations; comply with sustainability regulations and standards; enhance brand reputation and customer trust; and make informed decisions on sustainability investments and initiatives.

Introduction

LCAs have been in existence since the 1960s. The idea that led to the invention of LCAs was to create a tool whose primary assignment is to quantify and consequently facilitate appropriate management of waste and energy such that more general eco-efficiency measurement targets could be achieved (Thies et al., 2021). The ISO 14040/14044 standards provide the basis for LCSA's underlying process. The creation and evolution of industrial technologies has led to significant reconfiguration of the environment, causing alteration of nature and degradation of natural resources through pollution of air, water, and

land. Industries, particularly those involved in producing products that involve the utilization of chemicals and toxic metals and those involved in exploiting natural resources such as soil and clean water, fish stocks, and natural gas and oil indiscriminately, have come under fire for their unsustainable production processes that harm the ecosystem. However, these industries are now expected to adopt more environmentally friendly methods through the principles of "zero waste and minimal emissions and producer responsibility." Despite these efforts, the environmental effects of industrial activities are becoming increasingly difficult to control, as the negative impacts are not always immediately apparent and can take the form of cumulative and synergistic effects (Stokes & Horvath, 2006; Azapagic & Clift, 1999). For instance, local greenhouse gas emissions can contribute to the global greenhouse effect. Considering these challenges, the regulatory bodies responsible for protecting the environment must be proactive in their approach to assessing the environmental impact while taking into consideration financial, technical, and other criteria.

Life cycle sustainability assessment (LCSA) is an environmental management tool that evaluates regional and global environmental impacts associated with a product's entire life cycle, from raw material collection to production, use, and disposal (cradle to gate) (Azapagic & Clift, 1999; Curan, 2006; ISO, 2006a, b; EC, 2010). Curan (2006) highlighted the significance of LCSA in quantifying various adverse environmental impact categories, including climate change, photochemical oxidation potential, acidification, and eutrophication in aquatic environments. LCSA has gained widespread recognition in critical environmental assessments for sectors such as biofuels and agriculture, wastewater treatment systems, fish farming, and other important policies (Stokes & Horvath, 2006; De Vries & de Boer, 2010). To assess the impact of a product on the environment throughout its entire life cycle, from raw material collection to disposal, the concept of life cycle sustainability assessment (LCSA) was developed. LCSA can be differentiated from other environmental assessment metrics because it focuses on

identifying changes necessary to improve a product’s environmental performance and sustainability (ISO, 2006a, b; Guinée, 2016). Additionally, LCSA provides decision-makers with information on the environmental impacts of specific products, their performance, and alternative processing systems (ISO, 2006a, b; Thies et al., 2019, 2021). It quantifies the total inputs (energy and materials) and outputs (products, waste, and emissions) of a production system, known to impact the environment (ISO, 2006a, b; Yuan et al., 2012). The performance of an LCSA is divided into four main parts, as shown in Fig. 1.

Life cycle sustainability assessment is a comprehensive evaluation tool used to assess the environmental, social, and economic impacts of a product or system throughout its entire life cycle (ISO, 2017; Gundes, 2016). LCSA is used to identify areas for improvement and determine the sustainability of a product. The LCSA process is typically divided into several phases (Fig. 1), as follows.

Goal and Scope Definition In this phase, the purpose, scope, and objectives of the LCSA are defined, and stakeholders are identified (ISO, 2017). For instance, if the LCSA is being conducted for a new product, the goal could be to determine its environmental and social impact and identify ways to minimize it.

Inventory Analysis This phase involves collecting and analyzing data on the inputs and outputs of a product or system over its entire life cycle (ISO, 2017). These data from the inventory

are classified according to their potential environmental, economic, and social impacts in the following impact assessment (Thies et al., 2021). For instance, environmental data might include the amount of energy and materials used to produce a product and the amount of waste generated during its use and disposal (Jasch, 2000). These data can then be translated into emissions to and resource extractions from nature using databases such as ecoinvent.

Impact Assessment In this phase, the data collected in the previous phase and their underlying emissions and resource consumptions are used to assess the environmental, social, and economic impacts of the product or system (ISO, 2017). Environmental assessment involves using life cycle impact assessment (LCIA) methods to determine the environmental impact of a product (Muñoz et al., 2008).

This assessment stage takes into consideration the decision-makers’ preferences and the underlying uncertainty by integrating the numerous indicators from all three sustainability aspects to enhance decision-making. Each stage is followed by explanation and may be carried out in a series of repeats.

Such a method assigns characterization factors to all emissions and resource extractions and translates them into impact categories such as global warming, acidification, and eutrophication. For instance, a product’s total global warming potential might be determined by summing all greenhouse gas emissions considering their respective global warming potential (Christensen et al., 2009).

Evaluation This phase involves evaluating the sustainability of a product or system based on the results of the previous phases (ISO, 2017). The sustainability of a product can be determined by considering environmental, economic, and social impacts.

Interpretation In this final phase, recommendations are made for improving the sustainability of the product or system (ISO, 2017). These recommendations can be based on the results of the

Life Cycle Sustainability Assessment, Fig. 1 Definition of the LCSA phases. (Source: Thies et al., 2021)

L

previous phases and might include reducing the environmental impact, increasing resource efficiency, and improving social impact.

LCSA is conducted iteratively, and the phases should not be viewed as being linear and consecutive. To ensure accuracy, transparency, and relevance, a few things should be considered throughout the assessment. Those are the following.

Stakeholder engagement is a systematic process to gather their input and feedback on the LCSA process and results by influencing stakeholders. Stakeholders can include customers, suppliers, regulators, and other interested parties. For instance, a company might engage with customers to gather their opinions on the sustainability of its products and what improvements they would like to see.

Data quality assurance and verification ensure accuracy and completeness (ISO, 2017). This can involve validating the results of the LCSA to ensure that they are credible and reliable. For instance, a company might engage an independent third-party auditor to review its LCSA results and validate its findings.

Communication and Dissemination To make information and LCSA results widely available to stakeholders (ISO, 2017). This can be done through a variety of channels, including reports, presentations, and public meetings. For instance, a company might publish a sustainability report detailing the results of its LCSA and how it is working to improve the sustainability of its products.

Continual Improvement The LCSA process is not a one-time event but rather an ongoing process of continuous improvement. This involves regularly re-evaluating the sustainability of a product or system and making changes as needed to improve its sustainability over time. For instance, a company might conduct an LCSA every few years to assess the sustainability of its products and identify areas for improvement (Iribarren et al., 2016).

Software Tools and Database for LCSA

There are numerous software tools available for LCSA, each offering a different set of features and

capabilities. By choosing the right tool, organizations can streamline their LCSA process, improve the accuracy of their results, and communicate their environmental impact to stakeholders in a clear and concise manner. The following are some of the software tools commonly used in LCSA.

SimaPro SimaPro is a widely used life cycle sustainability assessment (LCSA) software tool that helps organizations assess the environmental impact of their products. The software features a database of life cycle inventory data, an impact assessment method, and a reporting tool, making it a comprehensive tool for conducting an LCSA.

GaBi GaBi is a software tool for LCSA that features a comprehensive database of life cycle inventory data, an impact assessment method, and a reporting tool. The software also provides users with a platform for conducting sensitivity analyses and Monte Carlo simulations, allowing them to understand the uncertainty and variability of their results. GaBi also analyzes economic as well as social impacts.

Building for Environmental and Economic Sustainability (BEES) BEES is a software tool for LCSA that integrates life cycle assessment with sustainability assessment (Whitehead et al., 2015). The software uses a database of life cycle inventory data and a comprehensive set of impact categories to assess the environmental impact of a product.

OpenLCA OpenLCA is an open-source software tool for LCSA that provides users with a database of life cycle inventory data and an impact assessment method (Wilson & Vasile, 2017). The software also features a reporting tool and allows for the integration of additional data sources and impact assessment methods.

EcoImpact EcoImpact is a software tool for LCSA that provides a comprehensive set of impact categories and a robust database of life cycle inventory data (Gava et al., 2018). The tool also features a reporting module that allows

users to communicate their results in a clear and concise manner.

BioScope BioScope is a software tool for LCSA specifically designed for the biobased industry. The tool provides a comprehensive set of impact categories and a database of life cycle inventory data, as well as a reporting module and the ability to integrate additional data sources and impact categories.

Many of these software tools offer a high degree of customization, allowing users to adapt the tool to meet their specific needs and requirements. For instance, a company might need to assess the sustainability of its products using a specific set of impact categories or data sources and software tools such as SimaPro or GaBi allow for this customization. Some software tools for LCSA can be integrated with other sustainability assessment tools, such as sustainability reporting software or environmental management systems. This integration allows for more streamlined and comprehensive approaches to sustainability assessment while also helping organizations to better understand the full picture of their sustainability impact. Software tools for LCSA have become increasingly user-friendly in recent years, making them accessible to a wider range of users. For instance, many software tools now feature intuitive interfaces and user-friendly data input methods, making the assessment process easier and more efficient. In addition, it is important to note that there is a growing interest in the development of cloud-based LCSA software tools, which allow for the collection, analysis, and communication of sustainability data in real time. These tools offer a more agile and efficient approach to LCSA, and they have the potential to revolutionize the way organizations access and communicate their sustainability impact.

Variant of LCSA

There are several variants of life cycle sustainability assessment (LCSA) that focus on different

aspects or stages of the life cycle of a product, service, or process. Here are a few examples.

Cradle-to-Grave LCSA Cradle-to-grave LCSA is a variant of LCSA that evaluates the sustainability impact of a product, service, or process from the time of its creation to its disposal or end of life (Hossaini et al., 2015). This variant focuses on the entire life cycle, including the extraction of raw materials, production, use, and disposal.

Cradle-to-Cradle LCSA Cradle-to-cradle LCSA is a variant of LCSA that evaluates the sustainability impact of a product, service, or process with the aim of creating a closed-loop system where materials are continuously recycled (Stillitano et al., 2022). This variant focuses on the entire life cycle, with a focus on material recovery and reuse and reducing waste and pollution.

Cradle-to-Gate LCSA Cradle-to-gate LCSA is a variant of LCSA that evaluates the sustainability impact of a product, service, or process up to the point of sale or delivery to the customer (Barni et al., 2018). This variant focuses on the production stage of the life cycle and does not consider the use and disposal stages.

Gate-to-Gate LCSA Gate-to-gate LCSA is a variant of LCSA that evaluates the sustainability impact of a product, service, or process from the point of production to the point of disposal or end of life. This variant focuses on the production and use stages of the life cycle and does not consider the extraction of raw materials and disposal stages.

End-of-Life LCSA End-of-life LCSA is a variant of LCSA that evaluates the sustainability impact of a product, service, or process only in the end-of-life stage, including disposal, recycling, and waste management (Hossaini et al., 2015). This variant focuses specifically on the environmental and social impacts of the disposal and waste management stages of the life cycle.

Applications of LCSA

LCSA is regarded as the application of system analysis on a product such that the interconnection between the life cycle chain of the product and the environmental impact that comes with it could be ascertained while providing conservation measures to ensure sustainable environments.

Life cycle sustainability assessment has a wide range of applications in different industries and sectors. Here are some of the key applications of LCSA.

Environmental Management LCSA can be used to evaluate the environmental impact of products, services, and processes and to identify areas for improvement. This can help organizations meet environmental regulations, reduce their carbon footprint, and improve their sustainability performance.

Supply Chain Management LCSA can be used to assess the sustainability impact of the supply chain, from raw material extraction to end-of-life disposal. This can help organizations identify areas for improvement and reduce the sustainability impact of their supply chain.

Product Design LCSA can be used during the product design phase to evaluate the sustainability impact of different design options and to optimize the design for sustainability. This can help organizations improve the sustainability performance of their products and reduce their environmental footprint.

Decision Making LCSA can be used to support decision-making in areas such as product development, supply chain management, and sustainability strategy. By providing a comprehensive view of the sustainability impact of different options, LCSA can help organizations make informed decisions that align with their sustainability goals.

Public Procurement LCSA can be used in public procurement processes to evaluate the

sustainability impact of products and services and to select suppliers and products that align with sustainability goals. This can help public organizations improve their sustainability performance and reduce their environmental footprint.

Investment Decision Making LCSA can be used in investment decision-making to evaluate the sustainability impact of potential investments and to select investments that align with sustainability goals. This can help investors improve their sustainability performance and reduce their environmental footprint.

Sustainability Reporting LCSA can be used in sustainability reporting to provide a comprehensive view of an organization's sustainability impact, including its environmental, social, and economic impact. This can help organizations communicate their sustainability performance to stakeholders and improve their reputation.

Environmental Impact Assessment LCSA can be used in environmental impact assessment to evaluate the sustainability impact of projects and to identify areas for improvement. This can help organizations reduce their environmental footprint and improve their sustainability performance.

Climate Change Mitigation and Adaptation LCSA can be used in climate change mitigation and adaptation to evaluate the sustainability impact of different mitigation and adaptation strategies and to optimize their sustainability performance.

Consumer Goods LCSA can be used to evaluate the sustainability impact of consumer goods, such as food, clothing, and electronics, and to identify areas for improvement.

Infrastructure and Construction LCSA can be used to evaluate the sustainability impact of infrastructure and construction projects, such as buildings, roads, and bridges, and to identify areas for improvement.

Energy and Utilities LCSA can be used to evaluate the sustainability impact of energy and utility systems, such as power plants, pipelines, and water treatment facilities, and to identify areas for improvement.

Agriculture and Land Use LCSA can be used to evaluate the sustainability impact of agriculture and land use practices, such as crop production, livestock production, and forest management, and to identify areas for improvement.

Waste Management LCSA can be used to evaluate the sustainability impact of waste management practices, such as recycling, composting, and landfill, and to identify areas for improvement.

Industrial Processes LCSA can be used to evaluate the sustainability impact of industrial processes, such as chemical manufacturing, oil refining, and metal processing, and to identify areas for improvement.

Health and Safety LCSA can be used to evaluate the sustainability impact of health and safety practices, such as workplace safety, product safety, and occupational health, and to identify areas for improvement.

Natural Resource Management LCSA can be used to evaluate the sustainability impact of natural resource management practices, such as fisheries, forestry, and mining, and to identify areas for improvement.

Challenges Involved with Life Cycle Sustainable Assessment

There are several challenges associated with life cycle sustainability assessment (LCSA), and some of them include the following.

Data Availability One of the biggest challenges of LCSA is the availability and quality of data. LCSA requires data on various aspects of a

product or system, including inputs, outputs, and environmental impact. These data may be difficult to obtain, incomplete, or unreliable.

Complexity LCSA is a complex process that requires expertise in many areas, including sustainability, life cycle assessment, and systems analysis. This can make it difficult for practitioners to understand and implement LCSA effectively.

Modeling LCSA requires the development of models to assess the sustainability impact of a product or system. These models can be complex and difficult to develop, especially for systems with multiple inputs, outputs, and pathways.

Integration LCSA must be integrated with other sustainability assessment methods and tools, such as life cycle assessment and sustainability impact assessment. This integration can be challenging, as each method and tool may use different data, assumptions, and methodologies.

Standardization There is currently a lack of standardization in LCSA, which can lead to inconsistent results and interpretations. This makes it difficult to compare LCSA results across products, systems, and sectors.

Cost LCSA can be a resource-intensive process, requiring significant investment in data collection, modeling, and analysis. This can be a challenge for organizations with limited resources.

Time LCSA is a time-consuming process that requires significant effort to gather data, develop models, and perform analyses. This can make it difficult for organizations to prioritize LCSA within their sustainability programs.

Relevance LCSA may not always provide relevant information for decision-making. For instance, LCSA also focus on environmental impacts but not address other sustainability dimensions, such as social and economic impacts.

Understanding There may be a lack of understanding among stakeholders, including customers, suppliers, regulators, and the public, of the purpose and results of LCSA. This can make it difficult to communicate the results and implications of LCSA effectively.

Accessibility LCSA can be a complex and technical process that is not accessible to many stakeholders. This can make it difficult to engage stakeholders in the LCSA process and to communicate the results and implications of LCSA effectively.

Interdisciplinary Approach LCSA requires an interdisciplinary approach involving experts from various fields, including sustainability, life cycle assessment, engineering, and business. This can be challenging for organizations to implement, as it requires coordination and collaboration across departments and functions.

Data Availability and Quality One of the biggest challenges in LCSA is obtaining accurate and relevant data on the environmental and social impacts of products and systems. This can be particularly difficult for new and emerging products, where data may not yet be available.

Modeling Complexity LCSA involves modeling complex systems and interactions between different components and processes. This can lead to uncertainty in the results and difficulty in capturing all relevant impacts and interactions.

Characteristics Specific to LCSA

- LCSA studies concentrate on the environmental, economic, and social impacts of a product or service. Factors responsible for adopting a particular LCSA approach include the combination of the cost involved, social implications, economic performance, and technical feasibility.

- LCSA connects these impacts to the system's function, which helps to simplify the comparison between available substitutes.
- LCSA helps to estimate balances over the entire life cycle of a product or service from the cradle to the grave, i.e., from the extraction of raw materials to disposal.
- LCSA quantifies all critical constraints (toxicity, global warming, eutrophication, etc.) associated with the environment.

Comparison with Other Environmental Analysis Tools

Apart from LCSA, there are several other tools available that may support decision-making by government, businesses, and consumers with regard to the environmental implications of that decision. The available tools can be streamlined into providing (1) a conceptual understanding of the system under study, (2) quantitative data on the environmental impacts of the studies, and (3) procedural guidance on how to use and classify the results of (2) (Fig. 2).

LCSA are part of the second step, as they provide quantified environmental impacts. Ecolabeling tools are part of the third step, typically dealing with a set of like products within a concise functional class, and aim to verify the environmental friendliness of a product compared to more harmful products. Another procedural tool is environmental audits, which evaluate the environmental performance of a solitary business and provide follow-up opinions.

These procedural approaches are frequently based on comprehensive environmental assessment tools, which include those described below:

- (i) LCSA estimates the substantial integral of resource uses, substance flows, and environmental aggregations to quantify several environmental constraints linked with a given task.
- (ii) A substance flow analysis (SFA) estimates the flows and environmental aggregations of an individual element, such as mercury, or a

group of substrates, such as inorganic nitrate compounds.

- (iii) A risk assessment (RA) investigates the associated risk or the probability of adverse impacts associated with installation (such as a nuclear power plant) or the risks involved with utilizing a chemical substance.
- (iv) Material flow analysis (MFA) systematically follows the flow of materials such as paper, glass, concrete, or plastics in the economy of a specific area.
- (v) A carbon footprint (CF) helps to ascertain total emissions of greenhouse gases either directly or indirectly associated with product, a human activity, or a business.
- (vi) A water footprint (WF) helps estimate the impacts of water usage and environmental exposures related to water physicochemistry.

The difference between LCA and EIA is illustrated in Fig. 3, indicating correlative temporal and spatial scales over which each tool is utilized. The LCA approach is primarily for estimating the life cycle of a product or service right, from the collection of raw materials (cradle) to the end of life or waste disposal (grave), either regional or on a global scale. In contrast, environmental impact assessment is limited to a specific site, such as the number of inhabitants close to the site, the distance between the site and residential neighborhoods, and the presence of ecosystems.

Summary

Globally, the LCA concept is essential for ascertaining the environmental performance of a product or service such that the impact generated will be easily measured and rectified. However, we recommend adopting ISO guidelines for LCA practice for accuracy or consistency and specific standardization toward an accepted LCA paradigm. Such a paradigm would help quantify several LCA flows, including boundary setting, impact categories and classification, normalization references, allocation policies, sensitivity analyses, and

aggregation of results when necessary. It is essential to comprehensively assess the environmental performance and impacts of products or services concerning whole supply chains (cradle to grave) and evaluate the tools, approaches, and methods to be used for global sustainability. The life cycle comprehensive sustainability assessment paradigm seems promising, and once it reaches maturity, the life cycle comprehensive sustainability assessment of product supply chains will be more feasible. Furthermore, incorporating a socioeconomic factor concerning LCA would make them more valuable for decision-makers, companies, consumers, and social and economic researchers.

Definition/Description

As society became more concerned with problems of natural resource scarcity and degradation of natural order, business organizations started to search for ways to reduce their negative environmental impact. One of the tools created for this exact purpose is the life-cycle analysis (LCA), sometimes referred to as life-cycle assessment. The phrase “life cycle” refers to the primary actions that take place over the span of a product’s lifetime, from its manufacture to its use and maintenance to its final disposal, including the extraction of raw materials. LCA is often a key technique for supporting sustainable development decision-making. It is a tool for assessing the potential environmental consequences of materials, products, processes, or activities. Importantly, LCA is a method for assessing the direct and indirect environmental impacts across the whole life cycle of a product system, from material acquisition to manufacturing, use, and disposal, that is, from cradle-to-grave. It considers all stages of a product’s life cycle from the standpoint of their interdependence, which means that one activity leads to the following one. LCA allows for the assessment of the total

environmental impacts from all stages of a product’s life cycle, including those that are typically overlooked in commercial analyses. This method provides a full view of the environmental elements of a product or process by considering impacts throughout the product life cycle, as well as a more accurate depiction of the true environmental trade-offs in product and process choices.

History of LCA (See Table 1)

The first study concerning the life-cycle analysis (LCA) was presented at the World Energy Conference back in 1963. Some other life-cycle-oriented methods were already developed through various cooperations between educational and industrial facilities in the 1960s. Resource and Environmental Profile Analysis (REPA) was one of those LCA precursors, while the term life-cycle assessment became a norm much later in the 1990s. In several years, the focus was on solid waste generation, which was seen as an issue, particularly in the United States, where landfilling was the predominant waste management strategy. Energy use was the focus of early investigations in earlier years when the price of oil was fluctuating or high. Emissions were also a source of public concern, which were judged to be sufficiently controlled by regulation and voluntary industry measures at times, but were later deemed to be quite problematic. Early methods of impact assessment tended to characterize emissions impacts as the amount of air or water required to dilute emissions to safe levels or below regulatory criteria.

Until the end of the 1990s, there were already dozens of functional methods for assessing impact. From this point, the only possible ambition became to lay the capstone by quantifying all relevant environmental impacts. The first methodology to achieve this to some degree was CML92, created by the Institute of Environmental Sciences from the Netherlands. In addition to this, the 1990s also saw the boom of a number of life-cycle inventory (LCI) databases. And with the release of the first ecoinvent database in 2003, covering all industrial sectors, the problem of

A framework for life cycle sustainability analysis was proposed	2008
International life cycle data system (ILCD) handbook published	2010
Product environmental footprint (PEF) and organization environmental footprint (OEF) guidelines published	2012 and later

(meta)data scarcity ceased to be an aggravating factor for the LCA (Hauschild et al. 2018).

Probably the most official recognition of this method began to happen in 1997 when the International Organization for Standardization (ISO) included LCA in the 14,000 series of environmental management standards.

Method

According to the US Environmental Protection Agency (EPA), “LCA is a technique to assess the environmental aspects and potential impacts associated with a product, process, or service, by:

- Compiling an inventory of relevant energy and material inputs and environmental releases

- Evaluating the potential environmental impacts associated with identified inputs and releases
- Interpreting the results to help you make a more informed decision” (EPA 2006)

The process of LCA illustrated in the Fig. 1 is conducted systematically through its four phases (or components): (1) goal definition and scoping, (2) inventory analysis, (3) impact assessment, and (4) interpretation.

1. Goal and Scope definition

- The first phase consists in explicating goals, objectives, and a scope of investigation. Here it is important to determine which product systems are going to be assessed and how. There are many variants of limited LCAs that differ in their scope of investigation such as

Life-Cycle Analysis, Fig. 1 General phases of LCA (ISO 2006)

cradle-to-grave, cradle-to-gate, cradle-to-cradle, gate-to-gate, or well-to-wheel.

2. Inventory Analysis

- Life-cycle Inventory (LCI) analysis is the most time-consuming phase of the LCA. LCI analysis mostly consists in collecting the information on elementary flows from all the processes of a certain product system.

3. Impact Assessment

- After LCI analysis accumulates and systematizes a full inventory of elementary flows, it becomes the basis for Life-cycle Impact Assessment (LCIA). Although it is largely automated by software, LCIA aims to assess the environmental significance of each elementary flow.

4. Interpretation

- In the last phase of LCA, all preceding phases are subjected to the control and reported with feedback. Ultimately, guidance is provided on how to draw conclusions derived from the previous phases of the interpretation and make suggestions based on the study's findings (ILCD, 2011).

Uses and Benefits

LCA is primarily used for helping decision makers select those materials, products, activities, or processes, which will inflict the least impact on the environment. It is massively used to support business strategy or R&D decisions as well. The information acquired from the LCA is usually combined with other relevant factors such as cost or availability before the decision is made.

According to the EPA, LCA serves as a necessary tool for avoiding shifting environmental problems from one place to another.

An LCA allows a decision maker to study an entire product system hence avoiding the suboptimization that could result if only a single process were the focus of the study. For example, when selecting between two rival products, it may appear that Option 1 is better for the environment because it generates less solid waste than Option 2. However, after performing an LCA it might be determined that the first option actually creates larger cradle-to-grave environmental impacts when measured across all three media (air, water, land) (e.g., it may cause more chemical emissions during the manufacturing stage). Therefore, the second product (that produces solid waste) may be viewed as producing less cradle-to-grave environmental harm or impact than the first technology because of its lower chemical emissions (EPA 2006).

Summary

Life Cycle Assessment (LCA) is a methodology used to evaluate the environmental impacts of a product or process throughout its entire life cycle, from the extraction of raw materials to the disposal or recycling of the product at the end of its useful life. The goal of LCA is to identify the environmental burdens associated with a product or process and to provide insights into opportunities for reducing these burdens. LCA consists of four main stages: goal and scope definition, inventory analysis, impact assessment, and interpretation. LCA is a useful tool for decision-making and sustainability assessment in various industries, such as manufacturing, construction, and transportation. It can help companies identify opportunities

for reducing their environmental footprint and improve their sustainability performance.

Life-Cycle Assessment

► Life-Cycle Analysis

Lifecycle of Sustainable Development

Fabiana Sciarelli
Department of Literary, Linguistic and
Comparative Studies, University of Naples
L'Orientale, Naples, Italy

Synonyms

Growth cycle; Sustainable growth cycle; Territory lifecycle

Definition

The life cycle is a fundamental tool of analysis that can be seen as the basis of the strategic

planning. In fact, if an organization understands at what point in its life cycle it is, it can design the strategic choices to be undertaken.

Furthermore, the life cycle provides forecasts on the strategic plan that must be implemented, creating a continuity between what has happened (the final life cycle) and what will happen (the estimated life cycle) in the life of the company (Volpato, 1995).

The traditional life cycle model (Frey, 2009) describes changes in a company as a sequence of development phases. As a rule, development is not considered only as a quantitative phenomenon (higher turnover, other customers, more products), but also a qualitative one (constant turnover, satisfied customers, products known to the public).

To represent the life cycle of a company, we use the Cartesian axes, setting the time on the horizontal axis and the company value on the vertical axis. The life cycle curve of a company is then divided into four phases: (1) start-up or foundation of the enterprise, (2) growth, (3) maturity, and (4) change.

Key Issue

It is clear that a life cycle can be an important political tool in the development of a country. In fact, to establish a good strategic plan for a transforming country, it is very important to know its current level of development and the possible future development stages (Sciarelli and Rinaldi, 2017, 2018).

In the case of the development of a country, obviously the life cycle has different characteristics. On the horizontal axis, we find the time, which will probably be in years. On the vertical axis, instead there is the Human Development Index, divided into low (HDI from 0.0 to 0.549), medium (HDI from 0.550 to 0.699), high (HDI from 0.700 to 0.799), and very high (>0.800). The intersection point between time and HDI divides the development life cycle into three phases plus one: start up, hang on, and self-development (or welfare).

The life cycle of development at time zero does not obviously correspond to the birth of the country as it happens for the life cycle of a company, but to the birth of the willing to develop (Sciarelli and Rinaldi, 2015).

The initial phase of the strategic development process, which would normally include the transition from a low to medium HDI, is the most complex phase, in which the contribution of skills and foreign capital is crucial in the success of the strategic plan and in achieving the desired results.

The hang-on phase is very delicate, as it includes a constant growth with a progressive abandonment of both economic and human foreign capital. At this stage, the country could maintain its HDI, consolidating its growth, or it could continue to grow up to a high HDI, using fewer foreign resources.

The third phase can include one of the two scenarios: self-development or welfare. The first represents an evolution of development towards the maintenance or growth of HDI, obtained in complete independence. In this phase, in fact, the government and the NGAs become the main agents of their own development. In the second Welfare scenario, the country's profile is instead reduced both in development and in autonomy, since it becomes dependent on foreign assistance. The end of the second phase and the beginning of the third are decisive, since the country chooses between independence and dependence on foreign countries. A linear curve, as imagined in the Fig. 1, however, is not easily obtained. In fact, in the long run, there is a risk of intervening conflicting factors, such as natural disasters (especially in some countries), changes in government, economic crises. It is therefore right to imagine that every 15 years this curve may encounter some moments of revaluation.

The life cycle of sustainable development is based on three main components: economy, health, and education. So, if we consider only economic development, then altered cycles like the so-called "flash in the pad" are possible, a cycle in which there is rapid growth and therefore an equally rapid decline. More irregular or

particularly slow life cycles, such as those of Ethiopia and Benin, or unbalanced life cycles like the Indians and Filipinos, even if they have reached an average, HDI still have a net imbalance in the economic variables.

If the tools for choosing the strategy are to be the right ones, the life cycle of development must be divided into three distinct life cycles: the life cycle of economic development, the life cycle of health development, and the life cycle of educational development. On the horizontal axis, we set the time and on the vertical the GNI per capita, life expectancy at birth, and the average school years.

These life cycles of the development phases will help to orientate themselves in the definition of the strategic plan, in particular in dealing with the areas of weakness and the elements of the imbalance of the overall development.

A limitation of the life cycle in comparing the development sectors is, however, the non-synchrony of the data. However, the analysis allows us to understand at what level of development the country was in the year preceding the formation of the strategy and, although this causes a slight delay in understanding events, it can be mitigated by data coming from an overall strategic analysis.

However, the development life cycle can also refer to a specific phase or a specific aspect of HDI. As a tool for strategic planning, it must also take into account the average human development influenced by the incidence of a predominant variable, indicative of a state of imbalance.

Summary

The lifecycle of sustainable development is the result of a hybridization of the management traditionally used for companies with the development of the territories. In fact, a simple management tool such as the life cycle of a company is used to define the life cycle of a country and the actions that can then make this sustainable.

The hybridization between traditional management, which we call micro, and territorial

Lifecycle of Sustainable Development, Fig. 1 Development lifecycle (Sciarelli and Rinaldi 2017)

management in fact creates strategic macro-management tools, such as the lifecycle of sustainable development, which can be fundamental for the best management of territories.

Definition/Description

Local Agenda 21 (LA21) is a program officially launched by the United Nations in 1992 to promote sustainable development at the local level. The program encourages local governments to create sustainable development plans and implement them through partnerships with local organizations and community groups. The goal of LA21 is to achieve sustainable development by integrating economic, social, and ecological factors into decision-making activities at the local community levels.

LA21 is based on the idea that local governments are in the best position to understand and address the specific sustainable development needs of their communities. LA21 encourages local governments to take a holistic approach to

sustainable development by addressing issues such as economic development, social inclusion, and environmental protection in an integrated way. One of the key elements of LA21 is the participation of local communities in the planning and implementation of sustainable development initiatives. This helps to ensure that the initiatives are responsive to the needs and priorities of the community and that they have the support from subsidiary levels of society. As LA21 is a voluntary program local governments are free to design and implement their own sustainable development initiatives based on the specific needs and priorities of their communities. The program provides guidance and support to local governments through training, networking, and information sharing.

Introduction

The Earth Summit was a major international conference that brought together representatives from governments, civil society, and the private sector to discuss global environmental and development issues. One of the main outcomes of the conference was the adoption of Agenda 21, a comprehensive action plan for sustainable development that addressed economic, social, and environmental issues.

The proclamation text of Agenda 21 published in June 1992 after the United Nations Conference on Environment & Development in Rio de Janeiro, states the following:

Agenda 21 addresses the pressing problems of today and also aims at preparing the world for the challenges of the next century. It reflects a global consensus and political commitment at the highest level on development and environmental cooperation. Its successful implementation is first and foremost the responsibility of Governments. National strategies, plans, policies, and processes are crucial in achieving this. International cooperation should support and supplement such national efforts. In this context, the United Nations system has a key role to play. Other international, regional, and subregional organizations are also called upon to contribute to this effort. The broadest public participation and the active involvement of the non-governmental organizations and other groups should also be encouraged. (Agenda 21, UN [1992](#), ch.1.3)

One of the key outcomes of the conference in Rio was the adoption of Agenda 21, which is a program that promotes sustainable development. A specific part of this program, called “Local Authorities’ initiatives in support of Agenda 21” (Chapter 28), played a significant role in inspiring the global Local Agenda 21 movement. According to the Secretary-General of the 1992 Earth Summit, Maurice Strong, Local Agenda 21 is one of the most promising and significant programs to have come out of the Earth Summit and is now being implemented by hundreds of local authorities worldwide. As Agenda 21 recognized that sustainable development was a global issue that required the participation and engagement of all sectors of society, including local governments, community organizations, and residents, LA21 was established as a way to promote the implementation of Agenda 21 at the local level.

The objectives of LA21 were stated in aforementioned Chapter 28:

- (a) By 1996, most local authorities in each country should have undertaken a consultative process with their populations and achieved a consensus on “a local Agenda 21” for the Community;
- (b) By 1993, the international community should have initiated a consultative process aimed at increasing cooperation between local authorities;
- (c) By 1994, representatives of associations of cities and other local authorities should have increased levels of cooperation and coordination with the goal of enhancing the exchange of information and experience among local authorities;
- (d) All local authorities in each country should be encouraged to implement and monitor programs which aim at ensuring that women and youth are represented in decisionmaking, planning and implementation processes. (Agenda 21, UN 1992, ch.28.2).

Overall, Local Agenda 21 is a program that helps the local government to create a plan and implement it in order to achieve sustainable development. It emphasizes the importance of

community engagement in the process and encourages the integration of economic, social, and environmental considerations in decision-making.

Achievements

Local Agenda 21 (LA21) has been implemented in many communities around the world and has had several notable achievements.

... in 1997 Local Agenda 21 activities were underway in more than 1800 local governments in 64 countries. Over 80% of the reported activities were taking place in 20 countries with established or nascent national Local Agenda 21 campaigns. A staggering 90% of initiatives were taking place in high-income countries. Those underway in middle- and low-income countries were less focused on environmental issues but aimed at a better integration of environmental, social, and economic issues, even if they included a shorter time perspective than those in high-income countries. (Rok and Kuhn 2012)

Some achievements include:

- Reducing greenhouse gas emissions: Many communities have implemented LA21 initiatives that have led to reductions in greenhouse gas emissions, such as energy-efficient building retrofits, the promotion of renewable energy, and transportation demand management.
- Improving air and water quality: LA21 initiatives have helped to improve air and water quality in many communities. For example, some communities have implemented rainwater harvesting systems to reduce the strain on local water resources, while others have developed green spaces and planted trees to help improve air quality.
- Promoting sustainable transportation: LA21 has helped to promote sustainable transportation options such as cycling and walking, through the creation of bike lanes and pedestrian-friendly streets, and through programs to encourage active transportation.
- Enhancing social inclusion: LA21 has helped to promote social inclusion by engaging marginalized groups in the planning and implementation of sustainable development initiatives.

- Advancing sustainable economic development: LA21 has helped to promote sustainable economic development by encouraging the growth of local economies and supporting the development of sustainable businesses and industries.
- Improving environmental quality: LA21 has helped to improve environmental quality by promoting conservation, reducing pollution, and protecting natural resources.

It is important to note that the achievements of Local Agenda 21 (LA21) vary depending on the specific community and the level of participation and engagement of the community members. Some local governments have implemented LA21 initiatives with great success, while others have struggled to gain traction.

Partnerships

Local Agenda 21 is a program that involves a wide range of participants. (LA21) is a program that involves a wide range of participants, including local governments, community organizations, residents, private sector, NGOs, civil society organizations, and international organizations. The program relies on the participation and engagement of all these groups to effectively promote sustainable development at the local level.

As stated in the official document:

Partnerships should be fostered among relevant organs and organizations such as UNDP, the United Nations Centre for Human Settlements (Habitat) and UNEP, the World Bank, regional banks, the International Union of Local Authorities, the World Association of the Major Metropolises, Summit of Great Cities of the World, the United Towns Organization and other relevant partners, with a view to mobilizing increased international support for local authority programs. (Agenda 21, UN 1992, ch.28.4)

Following this, partnerships are fostered to be found among:

- Local governments: Local governments are the primary participants in LA21. They are responsible for creating sustainable development

plans and implementing them through partnerships with other organizations and community groups.

- Community organizations: Community organizations, including non-profits, businesses, and grassroots groups, are important partners in LA21. They often provide valuable input on the specific needs and priorities of the community and help to engage residents in the planning and implementation of sustainable development initiatives.
- Residents: LA21 encourages development initiatives. This helps to ensure that the initiatives are responsive to get the participation of residents in the planning and implementation of sustainable needs and priorities of the community.
- Private sector: Private sector is also an important partner in LA21 as they can play a role in funding, implementing, and supporting sustainable development initiatives, and can also benefit from sustainable development goals.
- NGOs, Civil society organizations: NGOs and civil society organizations are also key partners in LA21, as they can provide expertise, support, and resources to the local government in implementing sustainable development plans.
- International organizations: International organizations, including the United Nations, can provide guidance and support to local governments through training, networking, and information sharing.

Partnerships between local governments and community organizations are a critical aspect of LA21. Local governments often provide the necessary resources and support for sustainable development initiatives, while community organizations provide the local knowledge and expertise needed to implement these initiatives.

Projects

The specific projects that are implemented under LA21 can vary widely depending on the needs and priorities of the community. Some examples

of major projects that have been implemented under LA21 include:

- **Green building retrofits:** Many local governments have implemented energy-efficient building retrofits as a way to reduce energy consumption and greenhouse gas emissions. These projects often involve the installation of energy-efficient lighting, heating, and cooling systems, as well as the use of sustainable building materials.
- **Renewable energy:** Many local governments have implemented renewable energy projects, such as the installation of solar panels, wind turbines, and geothermal systems, as a way to reduce their dependence on fossil fuels and promote sustainable energy use.
- **Sustainable transportation:** Many local governments have implemented sustainable transportation projects, such as the promotion of public transportation, bike-sharing programs, and the development of pedestrian-friendly streets, as a way to reduce traffic congestion and improve air quality.
- **Green spaces:** Many local governments have developed green spaces, such as parks, gardens, and community gardens, as a way to improve the quality of life for residents and promote biodiversity.
- **Water management:** Many local governments have implemented water management projects, such as rainwater harvesting, greywater recycling, and the construction of wetlands, as a way to conserve water and improve the quality of local water resources.
- **Community engagement:** Many local governments have implemented community engagement programs, such as public meetings, workshops, and education programs, as a way to engage residents in the planning and implementation of sustainable development initiatives.

These are just some examples of the major projects that have been implemented under the Local Agenda 21 (LA21) program; many other initiatives also have been taken to promote sustainable development in different communities (Coenen et. al. 1999).

LA21 in The Hague (HLA21) is one interesting example of public participation in local policy for sustainability. Public participation in The Hague was structured according to different themes, each to be developed by a working group. The project leader functioned as a representative of the municipal council but HLA21 has had little influence on municipal policy. The working groups mainly comprised individuals already active in other voluntary groups, while the health sector, lay citizens, and businesses were not reached. However, many ideas were generated “close to the ground” and some working groups managed to implement concrete projects. A network in which various citizens, politicians, organizations, and companies participate has recently been established (Andringa 1998).

Criticism and Effectiveness

Local Agenda 21 (LA21) is a voluntary program, and like any program, it has faced some criticism. Some of the main criticisms of LA21 include:

- **Lack of funding:** LA21 is a voluntary program, and many local governments have struggled to secure funding for sustainable development initiatives.
- **Limited participation:** Some critics have argued that LA21 has not been implemented effectively because of a lack of participation from local governments, community organizations, and residents.
- **Lack of specific guidelines:** LA21 is a flexible program, and some critics have argued that the lack of specific guidelines and targets has made it difficult for local governments to measure their progress and assess the effectiveness of their initiatives.
- **Lack of enforcement:** Some critics have argued that LA21 is not enforced, and that local governments are not held accountable for implementing sustainable development initiatives.
- **Limited Impact:** Some critics argue that LA21 has not been able to achieve significant impact in terms of sustainable development, as the

program is voluntary and not all local governments are participating or following it.

- Political concerns: LA21 has been criticized by some as a political agenda that is imposed on local governments by the United Nations, and that it is not flexible enough to accommodate local cultures, customs and traditions.

In his influential paper “Local Agenda 21: Substance or Spin?”, Selman (1998) concludes that although it is difficult to measure the effectiveness of Local Agenda 21 (LA 21), there is some evidence that it has been successful in certain areas. These areas include the development of strategies, promoting environmental awareness among citizens, involving various sectors, challenging traditional beliefs and practices, and supporting local government.

In the book *From the Earth Summit to Local Agenda 21: Working Towards Sustainable Development* Lafferty and Eckerberg (2013) conducted a research across nine countries and reported on the most outstanding aspects of implementing LA21 across local communities. They concluded that despite the disproportionate levels of implementation between countries, LA21 acquires more and more collaboration arrangements with governments and local authorities across Europe.

Despite criticisms, Local Agenda 21 (LA21) is still considered as a valuable tool for promoting sustainable development at the local level and many experts and organizations still support it as a way to achieve sustainable development goals. It is important to note that the effectiveness of LA21 varies depending on the specific community, the level of participation and engagement of the community members, and the resources available to implement sustainable development initiatives.

Summary

The program known as Local Agenda 21, or LA21, was first presented in 1992 at the United Nations Conference on Environment and Development. This program encourages community participation in decision-making processes regarding economic, social, and environmental issues with the goal of

promoting sustainable development at the local level. “Think globally, act locally” is a core principle of LA21, which aims to inspire local authorities, companies, and citizens to act locally to promote sustainable development. The program has been put into place in many nations around the world, and community members and stakeholders are essential to its success.

[Local food](#); [Local food systems](#)

Definition/Description

Local food systems refer to the production and consumption of food that has been grown or raised in close physical proximity to the consumer (Martinez et al. 2010). Although this is the primary and most commonly accepted definition, local food can also refer to food sold in local farmers’ markets or has a specific characteristic which makes the food particularly typical for a geographical location (Coelho et al. 2018).

The tendency for promotion of the consumption of locally grown fruits and vegetables, and the products of locally raised animals has been on the rise in recent decades. There has been a significant rise in demand for fresh local produce and other farm products (Pinchot 2014). Research shows that price premiums increase as the geographical scale of food production shrinks (Burnett et al. 2011).

Local food systems are considered to have a positive impact on environmental protection, as opposed to large international supply chains of food. They are also believed to be beneficial for economic development, as they are labor intensive, and provide employment of local producers. This is especially relevant and of greater importance to rural and nonurban areas (FAO 2017).

Economics of Local Food Systems

Local food is usually produced by a larger number of small-scale producers and farms (Pinchot 2014). While bigger producers tend to cover a wider geographical range of customers, local small-scale producers rely on the opportunities presented by shorter supply chains. Localizing production and distribution in one place is noted to lead to the elimination of intermediaries, which in terms lowers the final price of local food (European Network for Rural Development 2012).

An important aspect of the local food systems production is the lowering of coordination costs between producers and consumers. With the opportunity to communicate directly with consumers, local producers could redistribute their scarce resources to the production of more strongly preferred goods (Pinchot 2014). For these, and other reasons, more and more have been small and medium-sized companies (SMEs) considered a key part of local food systems promotion for enhancing regional economic development (Donald 2008). Local food systems are also considered to contribute to economic development through enhancing local entrepreneurial environments, fostering economic clusters and regional branding opportunities, as well as

promoting the rise in social capital and local quality of life (Hughes and Boys 2015).

Local food systems are considered one of the crucial elements for achieving economic growth in rural areas. Keeping a food market local provides an opportunity to local producers to acquire a larger market share. Local food production is related to growth in local output.

At the same time, recent trends in consumer preferences show that more consumers are now interested in greater transparency regarding the means in which food is produced and also how their purchasing decisions could support their values and beliefs about sustainability and healthy lifestyle, as well as contribute to the local economy (Moraghan et al. 2017). Examining consumer willingness-to-pay, it has been established that price premiums increase as the geographical scale shrinks; however, at a specific range of local scales, consumers remain equally willing to pay for local food (Burnett et al. 2011).

The consumers' willingness-to-pay for local food is determined by various factors. It has been proven that personal convictions, habits, and cognitive biases, such as being part of an environmental group or being raised on a farm have a positive correlation with higher willingness-to-pay for locally grown/locally raised food (Brown 2003).

In line with the change of consumer incentives, an increase in interest by both the public and the private sector in terms of financing local food enterprises and schemes has been identified (Moraghan et al. 2017). However, financing local food systems is still considered to be underdeveloped, as investors are generally still feeling uneasy in relation to the risk-to-reward ratio of local food systems enterprises (Moraghan et al. 2017).

Environmental Impact of Local Food Systems

Local food systems have been considered to be of great importance for lowering greenhouse gas emissions, since the supply chain is much

shorter, and therefore the environmental impact from transportation – much lower (Shindelar 2015).

This notion is intuitive, and it has become an integral part of the local food systems narrative in both economic and environmental terms. However, there is more to the story of food miles than just measuring the length of food travel environmental costs. Despite measuring the overall environmental impact of local food in terms of travel distance and food travel costs, this indicator has been considered as not extensively reliable, and a richer combination of spatially explicit life cycle assessment with analysis of social issues is needed in order to incorporate the full scale of the impact of local food systems on the environment (Edwards-Jones et al. 2008).

Local Food Systems and Sustainable Development

A distinct characteristic of a significant portion of the local food systems producers is the strive to create positive externalities by promotion of measurable social or environmental goals, such as pesticide-free production, fair on-farm labor practices, and expanded nutrition access for low-income households (Moraghan et al. 2017, p. 45).

Local food markets are markets in which small-scale and family farmers are considered to have a competitive advantage because the production of such products is mostly labor-intensive, as opposed to capital-intensive goods which generally are more characteristic of large-scale production (FAO 2017).

Local food systems are believed to be a powerful tool for poverty alleviation and agricultural development. The link between farmers and cities is believed to have a great impact on rural poverty alleviation in smaller and more economically underdeveloped regions (FAO 2017).

Also, local food systems have a positive impact on advancing food equity and social inclusion of vulnerable groups such as local farmers and small-scale food producers (FAO 2017).

Criticism of Local Food Systems

Although local food systems are perceived to be a viable solution to both social and environmental problems, the definition of what constitutes a local food system is the main problem for measuring the actual effects. If framed within the globalization context, the local food systems notion has been perceived as a reaction against the adverse effects of the globalization process (Hinrichs 2003).

The problem of the concept of local food stems from a social constructivist point of view where desirable social and environmental outcomes may not always fit neatly on the spatial content of “local” concept. Alongside the economic politics of the local food production, the social aspect of differentiation has to be taken into account, and the emerging new spatial concepts pose an obstacle, as the “local” scale is in fact a different perception to different social groups and social entities (Hinrichs 2003).

Summary

Local food systems are a topic of consideration for both market agents and policy makers. As demand for locally produced food has been rising significantly in recent decades, there have been a number of benefits outlined in terms of economic development and environmental impact.

Local food systems imply shorter supply chains, which in terms lowers the final price of the goods, and is thus beneficial to consumers. At the same time, a concern regarding the market power of resellers and end-sellers such as supermarkets has been raised.

Local food systems are one of the examples of demand-driven tendency which has an overall positive effect on the environment, with local food being more sustainable in terms of carbon emissions involved in its reaching to consumers.

[Lifestyles of Health and Sustainability](#)

Description

The trade term **Lifestyles of Health and Sustainability (LOHAS)** was coined in the late 1990s by publisher Natural Business Communication to define the rapidly emerging market for healthy and sustainable products and services (Emerich 2000). This term allows marketers to think collectively about how to communicate to LOHAS consumers regarding products and services that are designed or perceived to be environmentally conscious, sustainable, socially responsible, and healthier – both for individual consumers and the planet (French and Rogers 2006). To this end, LOHAS describes the sizable and diverse consumer groups who (1) share values in caring for personal health, social justice, and/or planetary sustainability, (2) make consumption decisions based on these shared values, and seek social change through their purchases (Cortese 2003; Everage 2002).

Ray and Anderson (2000, p.329) linked the expanding LOHAS industry in the United States to the demands of “Cultural Creatives” who value activism and idealism, engaged action, whole process learning, gender equality, globalism and ecology, authenticity, and spirituality. LOHAS has seen wide adoption in the United States, Europe, Asia, and Australia, often accompanied by adaptation to local culture and consumer needs.

What Is LOHAS

The consumers pursuing Lifestyles of Health and Sustainability defy conventional market segment boundaries, such as age, gender, income, nationality, or social status. Instead, Lifestyles of Health and Sustainability (LOHAS) consumers share a set of values on individual health and sustainable planet and make deliberate purchase decisions based on their values and leverage their purchasing power to induce social changes (Ray and Anderson 2000). According to Conscious Media (www.consciousmedia.com), an independent and privately held multimedia company that purchased Natural Business Communication in 2002, the LOHAS market presents five major themes:

- **Healthy Living:** Highly conscious about their physical health, LOHAS consumers often enter the lifestyle by choosing organic foods and natural products. Goods and services that facilitate a healthy diet and other health-enhancing behaviors constitute a major LOHAS market category.
- **Alternative Healthcare:** The health pursuits of many LOHAS consumers also include integrative healthcare and holistic disease prevention. They actively seek out information and services on holistic health and alternative healthcare.
- **Personal Development:** Recognizing the connection between their physical and mental health, many LOHAS consumers show a strong interest in personal growth. They are attracted to goods and services that offer

learning and new experiences. For example, books and multimedia on mind-body-emotion-spirit connections and life balance topics are popular among LOHAS consumers. So are yoga and tai chi classes.

- **Ecological Lifestyles:** Many LOHAS consumers are keenly aware of the link between their own health and the health of the home planet. They embrace environmentally friendly products, adopt environmentally conscious behavior such as recycling, and keep informed on ecological topics.
- **Sustainable Economy:** Influenced by their holistic worldview, many LOHAS consumers value the “triple bottom line” approach to doing business sustainably in terms of financial, environmental, and social performance. LOHAS consumers prefer goods and services offered by companies that invest responsibly, use renewable energy sources, and adopt fair and ethical business practices.

The LOHAS Media Activities

Natural Business Communication launched the *LOHAS Journal* in March 2000 as a trade publication for the LOHAS industry. The publication of the *LOHAS Journal* was suspended in 2008 due to lack of advertiser support for the print journal (Soref 2008). The founder of Natural Marketing Communications and editor-in-chief of the *LOHAS Journal*, Frank Lampe, admitted that the term LOHAS might be too broad, with too many categories included in it (Cortese 2003).

The LOHAS forum was an annual trade conference (Emerich 2011) that ran from 1998 to 2013 in Boulder, Colorado. The forum brought together progressive-minded business leaders of start-up companies, multinational corporations, investors, media, and nonprofits. The participants created dialogues around creative solutions and compare notes on how to reach a value-driven segment of consumers – the LOHAS market – who seemed attracted to products and services that mirrored their interest in health, environmental stewardship, social justice, personal development, and sustainable living (Pícha and Navrátil 2019).

The Natural Marketing Institute (NMI), an international strategic consulting company, partnered with Natural Business Communications to produce a series of market research reports focusing on understanding the LOHAS Market. Since the early 2000s, NMI has been publishing annual report on the state of sustainability in America (NMI 2021).

Since its origin in the United States in the 1990s, the term LOHAS has become increasingly popular globally. The term LOHAS was introduced into China in the mid-2000s and translated to Le Huo (“live happily”), which is perceived in accordance with many age-old good living habits (Qiu 2009). Since 2012, LOHAS Expo (樂活博覽) is the leading trade expo for “Organic, Health, and Green Living products” with the aim to promote LOHAS in Asia. The event has attracted a diverse array of well-known global enterprises and brands from countries and regions around the world – China, Korea, Japan, Australia, the Philippines, France, the United States, etc. (LOHAS Expo 2019).

LOHAS and Sustainable Marketplace

At the time of its launch in March 2000, the *LOHAS Journal* read: “LOHAS Journal is dedicated to the promotion of sustainable business as a way to fundamentally alter the landscape for economic, social and environmental change. Our mission is to educate our readers about the growing LOHAS industry and to inspire innovation, creativity and dialogue between the companies and individuals that make up this diverse market, fostering a new paradigm of sustainable-business practices that can help create positive change” (cited in Emerich 2011, p.160). LOHAS proponents therefore envision a collective sustainable marketplace where conscious businesses could market more effectively to LOHAS consumers through partnerships (Emerich 2011).

A new worldwide LOHAS market has been developed, where existing business and new entrants compete to serve the LOHAS consumer segments. Around the world, a growing list of products, services, and companies cater to the

needs and wants of LOHAS consumers (Kotler 2011). For example, the LOHAS industries represented a \$355 billion market in the United States in 2016 and a \$546 billion market worldwide (Hoffman 2018). In 2019, the NMI annual report of State of Sustainability in America categorized 23% of US consumers as LOHAS. In Japan, one survey found that 29% Japanese consumers share LOHAS values (Fukushi and Schumacher 2005). A 2015 study estimated that about 30% Hungarian consumers resemble LOHAS (Szakály et al. 2017).

Summary

The emergence of the term LOHAS (Lifestyles of Health and Sustainability) highlights the cultural changes in consumer beliefs and behaviors in the society. LOHAS consumers are characterized by their values on personal health and sustainable planet. The LOHAS market comprises a wide range of industries now participating in a marketplace driven by demand for health and sustainability. LOHAS has made its mark in changing conventional social and cultural structures through the interaction and coevolution of LOHAS consumers, LOHAS markets, and media.

Making Sense of CSR Reports: A Methodological Perspective from Semiotics

Kemi C. Yekini
School of Finance and Management, SOAS
University of London, London, UK

Synonyms

[Artificial intelligence](#); [CSR reports](#); [Semiology](#); [Semiotics](#); [Sense making](#)

Definition

Semiotics is a linguistic analytical tool that relates to how users of communicated information can draw meanings through the signs perceived from the information (Chandler [2007](#)). Semiotics look further than the content of the writings through the interactions of codes and linguistic principles and the use of logical discourses to make sense of the narratives, thus enabling users to extract deep meaning from the information (Yekini [2017](#)).

Introduction

Substantial work has been done in corporate social responsibility (CSR) reporting and communications, and diverse methodologies have been adopted in measuring, researching, and determining CSR disclosure quality. The quality of disclosure can be described as how well the information provided meets or exceeds users' expectations and enables them to derive meaningful insights for making informed decisions (Price and Shanks [2005](#)). Viewing disclosure quality in this manner portrays it as the value and comprehension that users can obtain from the information conveyed. Assessing the quality of CSR reports is crucial as they aim to demonstrate the fundamental principles of the organisation to users of annual reports, including investors and creditors. These reports present a chance for companies to articulate their values and guide the audience's

perceptions towards particular goals, such as gaining investments or fostering customer loyalty. Therefore, comprehending CSR information presented is crucial in evaluating the reports' quality.

Key Issues

However, various methods for analyzing CSR reports exist in the literature, including a substantive multidisciplinary interest regarding the best way to evaluate the information quality in annual and stand-alone sustainability reports. Consequently, extant studies have produced differing results due to the narrative nature of the disclosures. None of these studies, however, attempted to explore the efficacy of a linguistic-based approach. Yekini et al. (2021) argue that making sense of CSR communications will be better accomplished when the texts of the narratives are subjected to linguistic analysis. They, therefore, developed a CSR reports quality evaluation model employing a linguistic-based theoretical, analytical tool – semiotics. Linguistic-based approach to evaluating CSR reports is vastly gaining ground.

According to Catellani and Ihlen (2022), the CSR quality model developed by Yekini et al. (2021) is a significant contribution to the field of CSR communication research, serving as a valuable tool. It can be utilized as a qualitative analytical tool to assess the authenticity and openness of the organizational values conveyed in the reports and as a quantitative measure of CSR quality. As a quantitative measure, the model can generate data for statistical analysis by producing a quality score for CSR activities. This model presents a theoretical framework for determining the essential criteria to ensure the credibility and quality of information. Utilizing a linguistic-based method, the quality model has the potential to improve the evaluation of corporate narrative disclosure by enabling a thorough and structured analysis of the fundamental organizational values conveyed in the reports.

Given that semiotics is a well-established linguistic theory with a history of over a century and has been successfully applied to analyze sign-

based communications, the model is founded on a robust theoretical basis. This is particularly important because it provides distinctive insights into evaluating the quality of CSR communication and an effective way to generate a trend analysis of the firm's performance in each CSR theme (e.g., educational sponsorship). This could be a valuable approach to track the company's advancements and offer a chance to enhance its performance in the specific CSR domain. Additionally, it could serve as a useful tool for investors to make informed economic and social decisions, such as investing in socially responsible investments. Nonetheless, the sustainability of the CSR quality model is uncertain, given the rapid development of machine language and artificial intelligence.

Future Directions

The application of Artificial Intelligence (AI) is rapidly gaining ground in text analysis and mining and has become a potent tool for investigating human cognition. This development has urgent implications for semiotic applications, theories, and practices. Semioticians, therefore, need to braise up and respond to the AI challenge by revisiting the application of semiotics tools through the lens of AI if semiotics will maintain its relevance in any meaningful analytical way.

Summary

To summarize, semiotics offers a critical prospect to appraise the quality of CSR and other narrative disclosures in annual reports. However, its utilization is progressively declining due to the emergence of artificial intelligence and natural language processing. Nonetheless, while AI aims to create artificial intelligence that can outperform human intellect, semiotics, as a study of signs, is more applicable to comprehending human reasoning rather than artificial modeling of the human mind. Thus, semiotics can enhance the application of AI by offering insights into human semiosis, which is otherwise challenging to simulate.

is a specific Sustainable Development Goal (SDG 2) and underpins the other Sustainable Development Goals in building on the broader Millennium Development Goals. As a basis for sustainable management, it involves an aspiration to ensure constant access to sufficient and nutritious food for all by 2030. That requires action by public and private actors regarding nutrition education, reduction of marketing that fosters harmful consumption in both the global South and North, strengthening of corporate responsibility, national and international measures to ensure the affordability of food in times of disasters or conflicts, and prioritization of food production over other commodities such as biofuels. Achievement of SDG 2 potentially addresses human rights concerns, builds the legitimacy of domestic and global frameworks, and fosters sustained development in the global South beyond the agricultural sector. It however necessitates engagement with international commodity markets, given that malnutrition is as much a matter of distribution as it is of food production and political relationships that privilege large landholders.

Malnutrition and Sustainable Management

Bruce Baer Arnold
University of Canberra, Canberra, ACT, Australia

Synonyms

[Health](#); [Hunger](#); [Nutrition](#); [Poverty](#)

Definition/Description

The elimination of hunger and malnutrition (which encompasses both deficiency and obesity)

Introduction

Malnutrition has been a recurrent feature of history in all parts of the world over several millennia. On occasion, it has resulted in civil disorder, even regime change, as a failure to effectively address famine through food storage, imports and restrictions on profiteering resulted in the loss of legitimacy for rulers or capacity to resist conquest. In the past century, it has been addressed through private and public “famine relief” measures, in part inspired by reports of population-scale starvation in locations such as the Ukraine, China, and Sub-Saharan Africa (Götz et al. 2020; Hall-Matthews 1998; Murchadha 2011; de Waal 2005).

There has been growing recognition that malnutrition is determinative of health and productivity, with people who are undernourished being particularly susceptible to endemic/pandemic diseases and less likely to perform effectively in resource extraction, manufacturing, infrastructure

development, and administrative activity. There has also been increasing recognition that malnutrition as a focus for sustainable management involving consumers, governments, civil society bodies and corporations potentially involves “wicked problems” that are resistant to nonsustainable solutions such as donation of food in a crisis.

Malnutrition has often been understood as the absence of food, in other words absent or inadequate supply of grain and other commodity during a prolonged drought or as a result of an epidemic affecting a staple, for example, the 1845–1849 potato famine in Ireland (Murchadha 2011), in an environment of ecological fragility. From the perspective of sustainable management, fragility is likely to be salient because of climate change (Fraser 2006; Gillan and Lambert 2016). Supply problems have often been exacerbated by hoarding and profiteering, with the poor for example being unable to afford supplies held by elites (Dowlah 2006). An understanding of malnutrition can however be more nuanced, with an emphasis on sufficient healthy food, in other words avoidance of “junk food” choices that foster obesity and systemic noncommunicable health conditions such as diabetes and heart disease that are not readily addressed through public/private health services (Gómez 2021; Lobstein 2015; Lobstein and Cooper 2020; Williams et al. 2018) and that for example affect two fifths of adults in the United States (Hedley et al. 2004). Such avoidance involves mechanisms such as public education alongside nutritional labeling of processed foods, “fat” and “sugar” taxes that nudge both production and consumption (Fox et al. 2017), and initiatives to reduce “food deserts” (Cummins and Macintyre 2002) rather than land reform or large-scale humanitarian gifting of supplies as “famine relief” during crises. It also requires engagement with disagreements about “food versus fuel” in building sustainable energy (Thompson 2012; Tomei and Helliwell 2016).

Malnutrition, Development, and Sustainability

It has been estimated by the United Nations Standing Committee on Nutrition that around one-third

of the global population has some form of malnutrition (UNCSCN 2018). Although much of the scholarly literature and most public attention centers on poverty, poor nutrition, and public disorder in parts of the global South, it is noteworthy that the United Nations Food & Agricultural Organization (FAO) estimated in 2018 that 43 million people in the European Union are unable to afford regular quality meals every second day (FAO 2018). Nutritional disorders include stunting, reported as affecting over 30% of young children in Africa (DI 2018). Malnutrition is often associated with poverty in a cycle (Siddiqui et al. 2020) where deficits in feeding are exacerbated by, and in turn intensify, deficiencies regarding clean air and water, public hygiene, work/residential locations free from carcinogens and substances such as mercury, and a wage justice that permits sleep and recreation as one basis of health.

Theorists since at least the time of Malthus have recognized links between malnutrition (in particular large-scale starvation, highlighted in pre-Modern imagery about famine as one of the Four Horsemen of the Apocalypse), poverty, epidemics and perceived over-population (Connelly 2010; Cunningham and Grell 2000; Hartmann 1987). Responses have encompassed the development of public/private infrastructure for storage and distribution on a regional or global scale of agricultural commodities (notably grain) and processed food, investment in public health infrastructure such as water and sewerage networks, alongside research into specific nutritional disorders such as beri beri and community education about “eating healthy” or fertility control. There is acknowledgment that at a global scale much famine is a function of maldistribution, i.e., parts of the world on an ongoing or sporadic basis have insufficient food while other parts have surpluses, evident in for example individual consumers and retailers recurrently disposing of wasted food.

Rieff encapsulates concerns about the injustice of that malnutrition by referring to “the reproach of hunger,” noting the salience of markets, action by corporate producers and multinational commodity traders, failures by international organisations, underperformance by philanthrocapitalism and power relationships within much of the global

South that favor traditional elites rather than landless workers in unstable regimes that disregard human rights (Rieff 2015). His critique from a human rights perspective is consistent with work by Piketty and others on the implications of inequality (Piketty 2014, 2015; Boushey et al. 2017) and cautions about paternalism (de Waal 1989) or self-interest (Kennedy 1993; Kissi 2005; Varnis 1990).

The SDGs and Malnutrition

In fostering sustainable management, one response has been articulation of the high-level global Sustainable Development Goals (SDGs), an extension of the Millennium Development Goals (MDGs) and the World Health Assembly's endorsement in 2012 of six Global Nutrition Targets (GNTs) for improvement of maternal, infant, and young child nutrition by 2025 (de Romaña et al. 2021). The eight MDGs aimed to end extreme poverty and hunger, combat diseases such as Malaria and HIV, and foster other sustainability by 2015 (Fehling et al. 2013; Sachs 2012; Grosso et al. 2020; Gaiha 2003).

As noted elsewhere in this encyclopedia, the SDGs were adopted by the United Nations in 2015 to provide a common framework for international cooperation to promote sustainable development. All countries (high, middle and low income) are encouraged to reach 17 goals by 2030 (Sachs et al. 2019). That target was ambitious and in practice its achievement will be substantially affected by developments such as the COVID-19 pandemic and the effects of conflict in Ukraine alongside global warming. In discussing the MDGs, Sachs characterized them as

a type of global report card for the fight against poverty for the 15 years from 2000 to 2015. As with most report cards, they generate incentives to improve performance, even if not quite enough incentives for both rich and poor countries to produce a global class of straight-A students (Sachs 2012, p. 2206).

The challenge regarding malnutrition with the SDGs will correspondingly be to ensure all countries are at least straight-B students on an ongoing basis.

The SDGs are interrelated. Importantly, the second Sustainable Development Goal (SDG 2) specifically addresses both malnutrition and sustainability. It aspires to end all forms of hunger and malnutrition by 2030, ensuring that all people have access to sufficient and nutritious food at all times. As with the MDGs and the other SDGs, it involves collaborative action, in this instance inviting stakeholders to develop and implement policy recommendations and initiatives to ensure both food security and full nutrition. It specifically seeks to “End hunger, achieve food security and improved nutrition and promote sustainable agriculture.”

Nutrition directly affects SDGs 2 and 3 (health and well-being for all, at every stage of life) and indirectly influences five others. Almost all SDGs, for example SDG on reduction of inequality and 12 on responsible consumption and production, influence nutrition. Reducing nutritional deficits has the potential to improve learning performance among children (SDG 4), fostering gender equality (SDG 5) and escape from poverty (SDG 1), facilitating achievement of SDG 8 (“decent work and economic growth”) in a virtuous cycle (de Romaña et al. 2021). Achievement of SDG goals is also a prerequisite to achieving the 2012 Global Nutrition Targets.

As with the MDGs, SDG 2 does not refer specifically to the legal obligations of nations in relation to aims or targets. It does not specifically refer to a “right to food” and in practice a “right to health” has little traction in international law, particularly where there is state incapacity because of civil war or other conflict (Toben 2011).

Giving effect to SDG 2 experience with the MDGs suggests that sustainable management to address malnutrition is multifaceted, involving on-the-ground commitment by national governments alongside policy statements, funding by governments for nutritional support, law reform to address problems with practices such as sharecropping and hoarding or a focus on poppy rather than food production, investment in infrastructure for ongoing food supply, building human capacity, and strengthened transparency regarding the performance of international initiatives at the government and private (i.e., philanthropic) levels (Rieff 2015; Holsti 1986).

Summary

Malnutrition is a global rather than isolated problem that will necessarily solve itself through ongoing globalization within a neoliberal international order. It is more complex than notions of a one-off exceptional famine within a nation or region attributable to armed conflict or climatic events such as droughts and floods that impede production and distribution of food supplies from outside that location. As the SDGs recognize, malnutrition has implications for productivity, social equity and robustness in the face of epidemics. It more subtly raises questions about the capability and thus legitimacy of regimes, particularly in nations where elites eat well and eat securely while disadvantaged people experience food insecurity and insufficiency. Sustainable management to address malnutrition in both the global South and North requires national, international and private initiatives that involve collaborative activity (in contrast for example to traditional models of famine relief) evaluated using empirical data.

Definition

Management is the process of designing strategies that allow all the human, information, technological, and financial resources of the organizations to work together and harmoniously in the achievement of the proposed objectives (Ronda-Pupo and Guerra-Martins 2012). In a pragmatic way, management is in charge of the attention and resolution of the problems faced by the organizations in their path to achieve their goals (Blok 2020). Management exercises its function through the alignment of critical elements such as the mission, vision, values, strategies, and tactics of the organizations that allow the optimization of the diverse resources of the company.

Introduction

Management arises from the need to organize the activities of societies. This is reflected in the activities of planning, organization, leadership, and control of the organization's resources (Mintzberg 1973). In this context, management is one of the main human activities. Since man began to

organize as a society to achieve common goals, management has been of utmost importance to achieve social benefits. In history, basic management techniques have been identified since the year 3000 BC in what is now Iraq (Pindur et al. 1995). Since then various approaches have been presented for the study of this discipline. Management has been mainly associated with the business world; however all people in our daily lives carry out activities that require a greater or lesser degree of management processes.

Although management exists since humanity exists, Table 1 presents the historical evolution of management since it has historical records. It can be seen that this discipline has had important changes over 500 years, being its emergence as science from the beginning of the twentieth century with the work “The Principles of Scientific Management” (1911), whose author Taylor lays the foundations of Management As a Science.

The importance of management in organizations is vital; its existence ensures the proper functioning of organizations. Each organization needs direction, management provides this, in the absence of management resources remain static (will remain resources), and before an appropriate management these resources produce and contribute to achieve the objectives of the Organization (Ramasamy 2014).

The evolution of the discipline has presented nowadays its own and diverse complexity. This has made his study to be through the optics of various disciplines. For example, we are currently

talking about technology management (Nuscheler et al. 2019) or management of information technology (IT). Additionally, a dynamic and changing environment has played an important role in the new trends of management, which have not only changed their approaches but also how to manage resources.

In this order of ideas, we can say that for its study, management has had to be approached from a multidisciplinary and eclectic perspective. In this work we analyze the various schools that have approached management as science, so that they can have a better perspective on the usefulness of it. In addition, the main new trends in the science of management are also presented.

Key Issues

All the people in our daily lives do activities. These activities must follow an order mainly so that they can be achievable and beneficial for those who perform it; this is the most colloquial application of management. In relation to the modern management different schools have explained it.

The first of these is the school of “Scientific Management” based on the work of Frederick Taylor (1911), which focused on streamlining the resources of the organization in differentiating tasks to be able to produce more efficiently. The second school is the so-called “Classical Organization Theory School” where the contributions of

Management, Table 1 Management history

Era	Background to contemporary management	Classical	Human	Calculating	Values and beliefs	Future
Year	1530+	1910–30	1930–50	1950–70	1970–90	1990
Key ideas	Emphasis on materialism and individualism, industrial revolution, increasing prevalence and size of corporations	One best way, Scientific management, Time/Motion, Bureaucracy, Principles of Management	Interpersonal Aspects	Management Science	Social Construction, Institutionalization, Culture	CSR; stakeholder theory, well-being

Source: Dyck and Neubert (2008)

Henri Fayol (1916) and the sociologist Max Weber with his studies on Bureaucracy (1992) are mainly included. The third school is formed by the ideas of Elton Mayo (1933) and is called “School of Behaviour,” in addition to more recent ones such as the systems Approach (Bertalanffy 1938), Contingency theory (Lawrence and Lorsch 1967), and Chaos Theory (Nonaka 1988).

The first school is the classic vision of scientific management based on Taylor’s ideas, in his classic “The Principles of Scientific Management.” This school is considered as the formal start of management as a scientific discipline, mainly understood as management as a methodology, which sought through observation the systematization of various processes within organizations. It also enacted that work within the Organization should be divided among the best qualified people to carry it out. The second school is the “Classical Organization Theory” (1916) where the works of Max Weber and Henri Fayol are grouped mainly. This school focuses on the five main roles of management: predicting, planning, organizing, managing, coordinating, and controlling. This process is focused on each person having to perform specific tasks within the Organization to achieve the proposed objectives.

In addition, there is “the school of the behavior” “supported mainly in the contributions of Elton Mayo (1933). Their contributions are mainly focused on the primary groups in the industry context. In this order of ideas Mayo in

his studies discovered how the group they belong to affects its members. These schools are the main supporters of management today.

Previous administrative approaches present an important outline of what management is today. Basically they focus on three important factors, the control and efficiency of the resources as well as the management of contingencies that can be faced by the Organization and that affect the achievement of the objectives.

However, other key points are the terms administration and management; both terms are used as synonyms. Some authors consider that there is no difference between the terms. The main difference is that the administration is considered as an activity of the high management in the organizations, on the other hand the management is considered as an activity of the lower levels within the organization.

Table 2 illustrates the difference between management and administration from multiple points of view. It can be inferred that management applies to the lower levels of the organization, which are those that carry the weight of the implementation of strategies to achieve the objectives. On the contrary, management and administration are intimately linked because for management to work it must have a foundation in the administration. Therefore the relationship between the two is narrow and there is no marked difference in the functions and activities of each one. The administration’s theoretical livelihoods can also be for management.

Management, Table 2 Differences between administration and management

	Basis of distinction	Administration	Management
1	Policy and objectives	Determines policies to be followed and decide the objectives to be achieved	Implements the policy and achieve the objectives
2	Directing of human efforts	Not directly involved in the execution of plan and achievement objectives	Directly involves in the execution of plan and achieving objectives
3	Main functions	Planning, organizing, and staffing	Direction, motivation, and control
4	Level of executives	Top level executives	Acts as an agency
5	Position	Acts as a principal	Acts and agency
6	Knowledge	Requires administrative ability more than technical ability	Requires technical ability more than administrative ability

Source: Ramasamy (2014)

It is important to mention the hypothesis of the universality of the work of Management (Mintzberg 1973). This hypothesis supports that there are similarities in the activities and functions that managers perform, which serves to develop a general theory of administration. This hypothesis is based on the static balance that all institutions have to objective efficiency and this motivates managers to have similar practices regardless of the social and business contexts where they come from (Lubatkin et al. 1997).

What is stated in this section allows us to have a clearer picture of what management is. It is a complex discipline that has to work closely with others (Social Sciences, psychology, engineering, and so on), in addition to its close relationship with the administration. In this sense management, although it has a close relationship with the administration, is inserted within it. One of the best ways to understand management is through understanding discipline as universal and multidisciplinary, that is, it encompasses many areas of knowledge and is composed of diverse disciplines, approaches, and mixtures of areas of knowledge.

Future Directions

Management is made up of different disciplines and directly impacts the activities of others. That is why within future research it should focus on two main streams. First, to segment correctly the activities that it directs, for example: Management technology, strategic management, marketing management, public management, process management, supply chain management, talent management, among others, in order to be able to generate a greater impact in other disciplines that work in conjunction with management. Second, when proposing a research related to management, be clear about its roots. In other words, this refers to being able to understand the origin of the various social theories that have contributed to their training as discipline. This will provide the opportunity to give better results and contributions that improve the understanding of management.

It is also important to understand the role of managers in implementing strategies. It is unclear to what degree professionalization, age, academic degrees, and racial origins affect a person's ability to be a manager. Likewise is also relevant to carry out a cross-country study to understand the differences between management practices implemented by companies originating in emerging countries and companies originating in developed countries, since their contexts of origin to the companies to carry out particular practices. It is also important to understand how the management of a company that operates in different countries has to manage different strategies for each market where it operates.

Finally, we must consider that the environment is changing, coupled with the fact that management is not only applied to business and social sciences. It is important to investigate the adaptability of management to different scenarios and trends in different disciplines that can be presented. Understanding how the environment affects the advancement of management will strengthen it as a discipline.

Summary

The management nature is to solve problems that face the organizations in its broad spectrum of activities, operations and decisions. Also, management will be aligned to the tactics and strategies of the organizations, through the mission, vision, and values. Management is not only a business activity, it is a human activity that is present in our daily life, taking decisions, organizing, and planning. The roots of management as an academic discipline rely on the "Scientific Management" (Taylor 1911), "Classical Organization Theory School" (Fayol 1916), and the studies on Bureaucracy (Weber 1992). Nowadays management is focused on the control and efficiency of several assets in organizations and the way to face the uncertainty.

To understand the differences between administration and management are the central issues. The first is an activity in the high levels of the organizations, and the second is centered on

carrying out and executing the plans to achieve the proposed aims. To develop better strategies of management, it is important to understand the specific areas related to management (Marketing, technology, supply chain, government issues, etc.). Also, it is necessary to understand the roots of management, the environment where the organizations operate and the capability of managers to establish successful strategies for the growth and development in organizations.

Synonyms

[Business performance measurement](#); [Cost accounting](#); [Cost management](#); [Environmental management accounting](#); [Management control](#); [Managerial accounting](#); [Social management accounting](#); [Sustainability accounting](#); [Sustainability management accounting](#)

Definition

Management accounting provides financial and nonfinancial information for managers' planning, control, and decision-making, as well as for inventory valuation. The scope of management accounting has been recently increasing to include sustainability issues, involving various management accounting techniques, such as full-cost accounting, the sustainability assessment model, and material flow cost accounting. This increase in scope has created new opportunities and challenges for management accounting professionals, the management accountants, with regard to new potential organizational roles and challenges

involving the field of sustainability. These roles can range from leading the organizational efforts to measure and report sustainability performance, to interacting with other professionals specialized in sustainability and building bridges between the traditional area of management accounting and the field of sustainability. Another area under controversy concerns the skills required for the measurement and reporting of sustainability performance and whether management accountants or other professionals are better positioned to do so. Overall, in spite of the challenges and still unclear areas, the call is for management accounting, its practitioners and researchers, to continue to embrace the sustainable development agenda and concerns, in order to promote management decisions supporting a sustainable development of organizations and society.

Introduction

Management accounting is the organizational practice that provides information to assisting managers in their planning, control, and decision-making processes, in addition to providing information for the valuation of inventories and flows of goods, materials, and products. Management accounting is the field of accounting focused on organizations' internal users (as opposed to financial accounting, mainly concerned on reporting to external users). As part of an overall ► [management control system \(MCS\)](#), management accounting is a results control that monitors the performance of an organization and its sub-parts, across multiple dimensions.

It is now well accepted that management accounting deals with not only financial information and but also nonfinancial information, as nonfinancial information will sometimes be more suitable, relevant, or timely than financial information, when it comes to assisting managers in their efforts to run their organizations and generate value. Since sustainability has become prominent as a source of value for organizations and society, management accounting has been gradually encompassing information related to

this area as well, under labels such as sustainability management accounting or its specific sub-areas, environmental management accounting, and social management accounting (in addition to the traditional information of management accounting, mostly oriented towards an economic perspective of the organization). Indeed, this trend has opened up new potential roles for the management accounting professionals, the management accountants.

The ensuing text analyzes how the scope of management accounting has been expanding, with the most recent expansion being the sustainability area, a development which has promoted some convergence between external and internal accounting and reporting. A general description of environmental management accounting and social management accounting is followed by a description of several management accounting techniques that aim to promote sustainability-oriented decisions and outcomes within organizations: full-cost accounting; the sustainability assessment model; and material flow cost accounting. Then, a discussion of potential new sustainability-related roles of management accountants, and of opportunities and challenges for management accounting and its professionals, is presented. A brief summary closes the text.

Evolution and Enlargement of Management Accounting Towards Sustainability

Through embracing sustainability issues within management accounting, this field has arguably entered a new stage of development. To represent this change, Burns et al. (2013) proposed an extension of IFAC's (International Federation of Accountants) framework on the evolution of management accounting across the decades. From the management accounting traditional core area of cost determination and financial control, it started getting more involved in assisting planning and control, then later in waste reduction and then in value generation, examining drivers of customer and shareholder value. Burns et al. (2013)

suggested the emergence of a fifth stage, focused on sustainability, with a widened scope to include additional stakeholders and environmental and social impacts.

Accountants may support the design, implementation, running, and monitoring of sustainable business models by deploying various techniques, both in management accounting (for internal users) and financial accounting and reporting (for external users), in what can be broadly labeled as sustainability accounting. For external reporting purposes, important advances have been made, such as the development and the adoption of frameworks and guidelines for external sustainability reporting. Sustainability reports on organizations' ► [corporate social responsibility \(CSR\)](#) have been increasingly adopted, and the ► [Global Reporting Initiative \(GRI\)](#) has had a remarkable impact on developing sustainability reporting encompassing economic, environmental, and social performance and provides an extensive list of core indicators to be adopted. ► [Integrated reporting \(IR\)](#), promoted by the International Integrated Reporting Committee (IIRC), has also been increasingly adopted to replace separate reports on economic and on sustainability dimensions. Integrated reporting envisages communicating, in a single document and in an integrated way, how strategy, governance, performance, and prospects promote value creation, ranging from the short term to the long term. These developments make internal and external accounting and reporting less separated and, in particular, more interrelated than typically portrayed, as Contrafatto and Burns (2013, p. 362) commented on the specific case of sustainability: "sustainability is now a consideration that transcends both internal and external reporting processes which, in turn, possibly mirror each other more than ever before." While acknowledging this important convergence within sustainability accounting, this text particularly focuses on the production, analysis, and reporting of information to assist managers – i.e., specifically on management accounting – in planning, controlling, and taking decisions with a sustainability perspective. This is the realm of environmental and social management accounting, discussed next.

Environmental and Social Management Accounting

Environmental management accounting identifies, collects, and analyzes two types of information to inform managers' decisions. The first type concerns information on physical flows of energy, water and other materials, and has traditionally been dealt with by environmental managers; and the second type is financial information about costs and benefits of environmental impacts, therefore more closely related within the traditional financial focus of management accounting.

Environmental costs can be classified into four categories (similar to those often used to classify quality costs, as described by Burns et al. (2013)). The first two categories are related with efforts to improve the environmental performance of the organization by trying to avoid negative impacts: Prevention costs are related with the prevention of negative environmental impacts, and appraisal costs are related with assessing compliance with established policies. The third and fourth categories are related with organizational failures on environmental matters: internal failure costs, related with reducing environmental damages caused, but still within the boundaries of the organization, i.e., before they reach entities beyond the organization; and external failure costs, incurred due to environmental damage beyond the organization boundaries. For this classification to be possible, costing systems need to be structured in a way that enables the classification of the costs according to these categories. In as much as these are related with particular activities developed, an activity-based costing (ABC) system (Burns et al. 2013) may be useful for this purpose. However, the scope of which costs are to be considered can vary. While the above analysis typically refers to the economic costs incurred by the organization and captured by conventional costing systems, an alternative wider scope would include the environmental externalities of organizational activities, a scope which underlies the techniques discussed further below.

Social management accounting (SMA), as the label suggests, is focused on social costs. The measurement of social costs is substantially less

developed, both because they tend to be less translated into economic costs captured by conventional costing systems and also because the social externalities of organizational activities are challenging to capture. Bebbington and Thomson (2013) also point out that current management accounting research tends to place less attention on the social component of sustainability, when compared to the environmental component.

However, there has been a strong development towards an extended scope of accounting and reporting, both internally and externally, based on several management accounting techniques embracing a wider scope, including costs incurred both by the organization and beyond it, and including economic, environmental, and social perspectives. The techniques analyzed next (full-cost accounting, the sustainability assessment model, and material flow accounting and cost accounting) do not cover all existing techniques (for others, see, e.g., Gibassier and Alcouffe 2018 and Gond et al. 2012), but do provide a basis to understand how management accounting can contribute towards sustainability.

Full-Cost Accounting

Full-cost accounting (FCA) calculates the cost of production by including the use of environmental and social resources, going beyond the traditionally considered costs of economic resources, such as materials, labor, utilities, and machines. It therefore follows the notion of a ► [triple bottom line \(TBL\)](#) (Henriques and Richardson 2004). The aim is to account for externalities of an organization's activities, in particular negative environmental and social ones, such as pollution and unfair employment practices. As these externalities become included in the products (full) cost, and this cost is considered when determining profit margins and hence bonuses, managers have an additional (potentially economic) incentive to adopt practices with less environmental and social negative impacts. However, this technique requires the challenging task of monetizing the environmental and social costs.

Sustainability Assessment Model

The sustainability assessment model (SAM), originated at the oil company BP, aims at orienting project evaluation towards sustainability (Bebbington 2007). The SAM is based on FCA, therefore encompassing both economic costs and environmental and social costs, and it can be applied both at the investment stage and to ex-post evaluation.

Applying SAM requires four steps. The first is to define the cost objective, typically a particular project. The second step is to define the scope of analysis, encompassing the project full life cycle, i.e., all related upstream and downstream activities – for example, from prospection activities to batteries disposal, stretching “from cradle to grave.” The third step is to identify the impacts in terms of four dimensions: (a) economic, as traditionally estimated using historical or future economic flows; (b) resource use in excess of economic flows, in particular accounting for resource depletion and the negative externalities related to its unavailability for alternative uses; (c) environmental flows (e.g., emissions); and (d) social flows (e.g., jobs created and social impacts of products obtained through the project). The fourth and final step is required to enable direct comparisons and aggregation of the impacts in the four dimensions, by converting them into a common measure, typically money – i.e., by monetizing the impacts.

This last step, of monetizing the impacts, is highly complex due to the difficulty of ascribing a financial value to environmental and, in particular, social impacts, as already mentioned above. This acknowledged difficulty has prompted different approaches to manage sustainability. For example, one company developed the “product sustainability assessment tool” (PSAT), focused on new product development and adopting a product life cycle perspective (Riccaboni and Leone 2010). Importantly, PSAT does not monetize the different impacts and hence avoids the difficulties and criticisms associated with this last step. However, the lack of a single measure implies complex trade-offs across the perspectives and leads to ambiguity in decisions.

Material Flow Accounting and Cost Accounting

Material flow accounting, or input-output analysis, traces and analyzes the movement of all materials within an organization (Wagner and Enzler 2006). The underlying assumption is that all physical inputs sooner or later become outputs, leading to a balance between total inputs and total outputs. Inputs include all kinds of materials, as well as all sources of energy. Outputs can be products, waste, and emissions, with the former being labeled as “positive products” and the latter two labeled “negative products” and hence targeted for reduction.

Material flow cost accounting extends material flow accounting to trace and analyze the costs of the materials flows. It has a particular emphasis on a suitable assignment of costs to waste and emissions. The existence of this information, in particular if coupled with incentive systems, greatly promotes that managers take sustainability-enhancing decisions. However, Lang-Koetz et al. (2006) suggested that, when compared to the adoption of corporate input-output balances and environmental performance indicators (material and energy), flow cost accounting is mainly a supplement (rather than a substitute) opening up additional, purely economic impacts. However, they acknowledged that flow cost accounting could be suitable for companies having complex material flows and high material losses, in which this cost information may promote a considerable reduction in these losses. Overall, Lang-Koetz et al. (2006) considered that, alone, without other information such as specific environmental performance indicators, flow cost accounting is not sufficient to support environmental management. However, it is a specialized tool that may be a useful extension of existing costing systems and will provide information on some of the areas of a wider environmental performance indicator system. Clearly, this technique is highly demanding on organizational data. Therefore, it is crucial to embed it within, or at least tightly link it with, existing systems, in particular the adopted enterprise resource planning (ERP) systems and costing systems.

The Role of Management Accountants and Sustainability

As professionals traditionally involved in the production, analysis, and diffusion of information for managerial purposes, management accountants have seen their potential expanding, alongside the evolution of management accounting outlined at the start of this text. This text has discussed emerging techniques which are mostly developments or extensions of traditional management accounting techniques: full-cost accounting, as an extension to “conventional”/economic cost accounting; sustainability assessment model, as an extension to the investment appraisal in capital budgeting; and material flow cost accounting, as an extension of the tracking of materials and costs. Furthermore, the intervention of management accountants has been discussed in the context of their involvement in wider sustainability management issues, beyond the particular techniques discussed above.

Gibassier and Alcoufe (2018) recently summoned up the literature, knowledge, and calls about the roles of accountants (and management accountants) in this field. Professional accountancy bodies tend to suggest that accountants should take a leading and active role in implementing sustainability accounting, within a widened role to contribute to manage and report on all kinds of organizational resources and not only financial ones. Their knowledge about organizations’ business models and their involvement in risk management may also position them well to deal with increasingly relevant risks, such as climate risks, contributing to their organizations to better deal with those risks and capitalize on the opportunities these risks also create.

However, Gibassier and Alcouffe (2018) also state that surveys have continued to find low levels of involvement by accountants in sustainability issues (see also Accenture and CIMA 2011) and that accountants’ formal training in this area remains low. At the same time, they also point out to other research that portrait accountants as a change agent and a “euro-carbon translator”, both within and outside organizational boundaries. They can be proactive mediators,

actively engaging with other professionals and bridging their traditional accounting area and the sustainability area. However, just like in the widely discussed evolution of management accountants into a more “business partner” role (Burns et al. 2013), there are challenges in embracing new areas, not only related with the required skills but also due to the competition of other professional areas (e.g., engineers) (Gibassier and Alcouffe 2018).

An Overview of the Contribution of Management Accounting Towards Sustainability

Management accounting and its professionals have the potential to contribute towards a more sustainable organizational behavior, through the information and managerial incentives they provide (see, e.g., the various papers in the 2013 special issue of *Management Accounting Review*). Nevertheless, Bebbington and Thomson (2013) also consider that current efforts in accounting and management accounting (and research in this field) fall short of what is needed to improve and learn about sustainable development (see also Gibassier and Alcouffe (2018) and the similar comment above of Lang-Koetz et al. (2006)). At the same time, Bebbington and Thomson (2013, p. 282) also recognize that “[a]ccounting, however, is a crucial technology that might support sustainable development transitions as long as it infuses the rationales and concerns” of sustainable development thinking.

The challenge is therefore set for practitioners and academics to more deeply engage with sustainable development concerns and literature, in their efforts to further develop management accounting practices and research to contribute towards more sustainable organizations and societies.

Summary

Both internal and external accounting have increasingly widened their scope to embrace sustainability and contribute to orient their organizations into a path of sustainable development, for

themselves and to the wider society. Focusing on management accounting and its sub-areas of environmental management accounting and social management accounting, this text introduced some techniques in this area, such as full-cost accounting, the sustainability assessment model, and material flow cost accounting. The professionals in this field, the management accountants, are faced with a set of opportunities and challenges with regard to the type and to the depth of their involvement in the area of sustainability. However, overall, the call is for management accounting practitioners and researchers to increase their involvement with the sustainable development agenda and contribute towards more sustainable organizations and hence to a more sustainable world.

Definition

Management control systems (MCS) are mechanisms aiming to influence managers' and employees' behaviors, in order to achieve the organization's objectives and strategies. With regard to the increasingly important sustainability dimension, there is the challenge to translate its broad objectives and strategies into daily practices across the organization. To fill this gap, MCS, or more specifically sustainability control systems (SCS), constitutes an array of diversified mechanisms aiming to promote alignment between sustainability-oriented objectives and behaviors in organizations.

Introduction

► [Management Control Systems](#) (MCS) are commonly defined as organizational mechanisms promoting that managers and employees work toward the organization's objectives and strategies. In short, MCS are ways to influence behaviors (Gond et al. 2012; Merchant and van der Stede 2018). To achieve this, the definition of MCS should be based on, and aligned with, pre-defined organizational objectives and strategies. Therefore, strategically aligned and well-designed and implemented MCS can contribute to the successful attainment of strategic objectives.

The overwhelming rise of sustainability concerns, from governments to individuals, has made organizations incorporate sustainability dimensions in their objectives and strategies. Organizations are increasingly realizing that by behaving in a sustainable way, they will benefit themselves, their stakeholders, and society as a whole. However, like with any other type of objectives and strategies, it is necessary to design effective ways to transpose those objectives and strategies, typically of a high-level nature, into lower-level mechanisms with an effective impact on managers' and employees' decisions and behaviors (Crutzen et al. 2017). This is the role that MCS aim to play. Moon et al. (2011, p. 2) call for “integrating sustainability within management control, rather than simply relying on discourse

to deliver a triple rather than a single bottom line.” In fact, embedding sustainability in everyday business practices is an important requirement to manage sustainability (e.g., Morioka and Carvalho 2016) but often missing, as evidenced by Bonini et al. (2010). Therefore, to successfully promote sustainability-oriented decisions and behaviors in organizations, it is important to consider what management controls are available and can be mobilized to achieve that aim.

Organizations have largely understood the need to adopt controls regarding sustainability (Battaglia et al. 2016; Bouten and Hoozée 2016; Crutzen et al. 2017; Gond et al. 2012; Morioka and Carvalho 2016). Some organizations have developed specific systems focused on environmental and social issues, typically labeled sustainability control systems (SCS) (Moon et al. 2011; Battaglia et al. 2016); others have addressed these issues within the overall MCS. Indeed, SCS may be separated or integrated with MCS, in various degrees. For simplicity, since the ensuing discussion will analyze classifications and issues largely applicable to both MCS and SCS, it will typically use the term “management controls” in a broader sense, including also sustainability controls, unless the discussion specifically addresses comparisons and relations between MCS and SCS.

To provide an overview of potential controls to draw upon, the various forms of management controls are discussed next, followed by the distinction between formal and informal controls. The following sections discuss the control mix, the issue of complementarity and substitution between controls, and the distinction between systems and packages of controls. The final sections discuss the degree of integration between MCS and SCS, how they are used and what consequences may arise for the development, and outcomes of sustainability strategies, closing with a summary of the text.

Forms of Management Controls

A well-established classification of forms of controls (Merchant and van der Stede 2018) identifies action controls, personnel controls, and results

controls. Action controls view performance in terms of a process or action and try to ensure that employees carry out certain actions considered and defined as desirable. This type of controls requires their designers to know the specific actions that are desirable for a given situation and purpose and be able to assess if those specific actions were indeed taken (Merchant and van der Stede 2018). Examples of action controls include structural configurations limiting how machines work, passwords to limit access to certain physical or virtual spaces, checklists to be reviewed and complied with when performing activities, and so on.

Numerous action controls aiming to promote sustainability-enhancing behaviors exist, regardless of whether they are included in the overall MCS or set out in specific SCS. As mere illustrations, some examples are provided. A machine may be parameterized in such a way as to limit its operation speed to a certain level in order to protect the workers’ safety or to prevent pollution emissions considered to be excessive. Employees or project teams may need to go through a number of checks when performing an operational activity or taking a decision (e.g., on waste handling), requiring them to analyze and record (e.g., in an information system) the sustainability impacts associated with that activity or decision; the possession of that information would then orient them towards the best outcome in terms of sustainability. Therefore, action controls can focus not only on the actions that have a direct impact upon the final result (the waste management activity or decision) but also on preceding actions (the production of information relevant for decisions).

Personnel controls are a second form of controls. Personnel control relies on self-monitoring or monitoring through emotional or social mechanisms. Personal motivation, either intrinsic or related types of motivation, and individuals’ commitment to a particular objective are powerful mechanisms to guide individuals to act in a certain way. The search for acceptance within a social context in which emotional ties and peer monitoring are important is another example of a personnel control mechanism. Overall, personnel controls are achieved through hiring decisions, training, and other human resource mechanisms.

Personnel controls may be an increasingly effective form of promoting sustainability within organizations, as sustainability concerns become more widespread within society and among organizations' employees. In this context, business decisions and actions are more likely to be influenced by forms of motivation that lie between purely internal and purely external motivation, namely, "introjection (motivation based on avoidance of guilt, shame or disapproval) and identification (motivation based on congruence with one's values or goals)" (Adler and Chen 2011, p. 64). The broad term of ► **"Organizational Culture"** has been used to encompass many of the components of personnel control, such as shared values, beliefs, symbols, rituals, and ceremonies, features that have been found to be relevant in promoting sustainability objectives (e.g., Bouten and Hoozée 2016).

Results controls are the third form of controls. Here, obtained results, not their causes or means, are the only object of analysis and control. Results controls are the most traditional form of management control. From an economic and financial perspective, there are well-established indicators, techniques, systems, and routines to monitor performance. In the sustainability area, this type of control has long been adopted as well, when sustainability-related KPIs ("Sustainability and Key Performance Indicators" and "Key Performance Indicators (KPIs), for CSR") are collected, within specific SCS or integrated within the overall MCS.

Formal and Informal Controls

Controls can be formal or informal. Formal controls are purposefully designed and include explicit organizational structures, techniques, routines, policies, processes, and procedures. Cybernetic systems, such as accounting and budgeting systems, and other systems of "counting" for any particular aspect of organizational performance (such as sustainability) are examples of formal systems. Informal controls may be purposefully developed or may simply emerge out of organizational dynamics, beyond an explicit direction set

by top management. They include unwritten policies, beliefs, and values making up organizational culture (Crutzen et al. 2017; Malmi and Brown 2008; Merchant and van der Stede 2018). Therefore, the existence of these two types of controls, which may or may not be aligned given their nature, origin, and development, must be considered when defining controls for sustainability. For example, Crutzen et al. (2017), while stating that the large companies they studied adopted both formal and informal controls to achieve sustainability goals, stressed that managers tended to privilege either one or the other; furthermore, most managers believed that informal controls could be more effective than formal controls in influencing sustainability-relevant behavior.

The Choice of a Mix of Controls

MCSs typically cannot guarantee that the desired outcomes will indeed be achieved – in fact, neither one individual MC in isolation nor a massive amount of MCs. Even those control devices that may seem not possible to circumvent (e.g., a password barring unauthorized individuals from accessing an IT system or a part of it) typically can indeed be circumvented (e.g., when passwords are shared between authorized and unauthorized individuals). Results controls, although they have the appeal to focus on the outcomes considered most important for the defined objectives, suffer from a number of well-documented shortcomings. One of these shortcomings is promoting an excessive managerial focus on the output indicators being monitored, while neglecting other (nonmeasured) areas – an effect known as myopia bias.

The sustainability area is clearly susceptible to this risk of myopia bias. The multiple areas involved in sustainability, requiring different indicators ("Sustainability and Key Performance Indicators" and "Key Performance Indicators (KPIs), for CSR") and even expressed in different measurement units, make an aggregation of overall performance extremely difficult or even impossible. Decisions and their consequences on the

multiple areas of sustainability are likely to be interdependent, since improvements in one area may potentially cause deterioration in other areas; therefore, trade-offs are difficult to make on an objective basis. And if results controls and the selected indicators focus on a limited area, there is the risk that employees neglect the areas where adverse (but unmonitored) consequences arise.

Given the unavoidable limitation of every particular indicator, control, or even form of control, there is a general agreement that organizations should not rely on one single mechanism. Instead, using a mix of indicators, controls, and forms of controls is typically recommended, both in MCS and SCS. However, this does not mean enacting all possible ways of control, since this would be both unpractical and even counterproductive. Therefore, there is the need to consider the overall control mechanisms available, those already in place, and hence the overall control mix. This implies understanding the potential and shortcomings of each one and, importantly, the way they may interact and may be complementary or substitutes.

Complementarity and Substitution Between Controls

Determining the control mix requires, among other things, to understand the relationship between the consequences (beneficial or detrimental) of each control, in terms of whether the various controls may be complementary or substitutes (Grabner and Moers 2013).

Two controls are complementary if the benefits of using one control increase the benefits of using another one. For example, the benefits of providing additional training on sustainability issues are likely to increase the benefits of providing employees with more information about key performance indicators to assist them in their decision making. On the contrary, two controls are substitutes if the benefits of using one control decrease due to the benefits of using another one. For example, let us suppose that effective results controls can be used, through measuring sustainability performance and tying it to

incentives actually effective in motivating employees' behavior – for example, rewards of financial or nonfinancial nature to reduce waste. In that case, the benefits (and hence of the need) of using action controls to directly lead employees to adopt certain desirable actions may be lower. Likewise, and inversely, the benefits of using effective action controls may reduce the benefits from results controls. Of course, whether the relationship between controls is one of complementarity or substitution can only be established upon the particular controls deployed in particular settings. Finally, the coexistence of substitute controls is not necessarily negative: While the benefits of one control reduce the benefits of the other, the total benefit obtained may increase when compared to having only one of them. Therefore, organizations wishing to reinforce the control of a particular area may be willing to have substitute controls in place, accepting, for example, some overlap and redundancy between those controls.

These effects of substitution and complementarity between particular controls within an overall control mix have been also found in the sustainability area. For example, Crutzen et al. (2017) found that organizations with pronounced formal controls tended to have less developed informal controls; those with pronounced cultural controls tended to have less developed formal controls; and they did not find organizations adopting both a complete package of formal and informal sustainability controls.

Systems Versus Packages of Controls

The term “management control *systems*” (or, if specific to the field of sustainability, SCS) can suggest that organizations deploy controls in a carefully planned way to make them work in a fully coordinated and consistent way, collectively constituting a “system.” In such a situation, organizations would tend to have ideal mixes of controls – assuming that the control designers did make the best choices. However, in practice, different controls and systems are often introduced in organizations by different actors and interest

groups throughout the years; therefore, in a given organization, existing controls in their entirety should not be considered to be a single system but instead as a *package* of systems (Malmi and Brown 2008, p. 291). In a real-world view, it should be recognized that “suboptimal” assemblages of controls may be in place within an organization, as packages resulting from ongoing cumulative processes of change. As sustainability is gradually entering the concerns, objectives, and practices of organizations, we can expect packages of controls to be present – that is, representing an assemblage of controls introduced and mobilized by multiple actors throughout the years.

Based on these insights, Malmi and Brown (2008) suggested a framework widely adopted in the control literature, including five main control mechanisms: planning; cybernetic controls; reward and compensation; administrative controls; and cultural controls. Malmi and Brown’s (2008) framework reflects the richness and complexity of control in organizations. Controls may address actions, personnel characteristics, or results obtained; they may be formal or informal; and there may be a mix of multiple controls, potentially with relationships of substitution or complementarity, in an assemblage which may possess characteristics more aligned with a system or a package. This framework has been recently applied to sustainability by Crutzen et al. (2017) (see Gond et al. 2012, for examples of sustainability control systems across the Planning, Cybernetic Controls and Reward and Compensation categories). Crutzen et al. (2017) concluded that the usage of multiple controls was beneficial given the existence of complementarity relationships, with controls reinforcing each other. However, as already mentioned above, their finding that companies tended to privilege either formal or informal controls means that some substitution effects are also present and taken into account by organizations when determining the control mix.

Different Uses of Management Controls

In addition to the choice of *which* management controls are adopted and available to be used,

another crucial variable are the managerial intentions behind their adoption and *how* these controls are actually used. Simons’ (1995) seminal framework classified controls themselves as being diagnostic or interactive. However, Tessier and Otley (2012) suggested not applying this label to controls themselves but instead applying it to describe how controls are used. As such, Tessier and Otley (2012) highlighted that all controls can be used diagnostically or interactively. A diagnostic use refers to controlling the implementation of a given strategy, while an interactive use aims at fostering learning and strategy renewal.

The next section draws upon key control concepts above and explores them within the context of sustainability strategy. In particular, it draws upon a particular study to highlight that success of sustainability strategies is dependent on the mobilization of multiple controls, suitably integrated and used, to promote the desired influence over employees and managers and hence achieve the desired sustainability objectives and strategies.

Different Integration and Uses of MCS and SCS: Consequences for Sustainability Strategies

Moon et al. (2011) analyzed and related the sustainability strategies of three UK companies and their various control systems. They studied these companies’ more “conventional” MCS, depicted as those oriented toward economic performance; their SCS, focusing on environmental and social issues; and the relation between the two. In particular, they studied the integration of MCS and SCS (defined as the degree of overlap between them) and whether MCS and SCS were used diagnostically or interactively. Relating these variables (the overall level of integration and diagnostic or interactive uses of MCS and SCS) enabled the authors to identify eight different configurations of sustainability strategic integration through management control (see also Gond et al. 2012, for a more in-depth analysis of these configurations) (Table 1).

This study shows that the eight possible configurations have different outcomes, with

Management Control Systems and Sustainability, Table 1 Configurations of sustainability strategic integration through management control. (Source: Moon et al. 2011, p. 3, adapted)

Overall level of control systems integration	Use of systems		Configuration
	Management control system	Sustainability control system	
Low	Diagnostic	Diagnostic	Dormant decoupled strategy
Low	Interactive	Diagnostic	Compliance-driven sustainability strategy
Low	Diagnostic	Interactive	Strategy emergence through sustainability
Low	Interactive	Interactive	Schizoid sustainability strategy
High	Diagnostic	Diagnostic	Dormant integrated strategy
High	Interactive	Diagnostic	Peripheral sustainability integration
High	Diagnostic	Interactive	Sustainability-driven organizational strategy
High	Interactive	Interactive	Integrated sustainability strategy

sustainable strategy making being more or less robust across the various alternatives. That is, the control mix, the extent to which the various controls are integrated, and the way they are used are important determinants of the types of sustainable strategy pursued, with very different contents and effectiveness attached to each type. Simply adding more controls, without considering the overall organizational control context, may lead to a package of controls which may be an inefficient mix. The key practical implication for organizations is that mobilizing an SCS may not be sufficient, because it may remain peripheral in practice, while the conventional, deeply rooted MCS remains the main influence over actors' decisions. Therefore, Moon et al. (2011) (see also Gond et al. 2012) stress the need to integrate sustainability and SCS within the overall control systems (see also, e.g., Morioka and Carvalho 2016) and in particular within the main MCS used interactively by managers.

Summary

This text has introduced key concepts of management control to assist in the design of effective ways to achieve sustainability strategies and objectives. As sustainability concerns become more prevalent in society and organizations,

there is the need to create mechanisms that promote that decisions and practices of organizations and their actors are aligned with, and lead to, such strategies and objectives.

Therefore, this text discussed fundamental concepts and distinctions in management control and related them with, and applied them to, the area of sustainability. The reviewed studies reveal substantial diversity, complexity, and richness in the array of available options. Organizations need to evaluate multiple forms of control, formal or informal, when determining their control mix, including those in sustainability-related matters. The various controls may be complementary or substitutes, and the overall control configuration may resemble more a deliberate, organized control "system" or an emerging assemblage of a control "package." Finally, the integration of the general MCS and the specific SCS, as well as the uses (diagnostic or interactive) given by managers to the various controls, are important to determine the types of sustainable strategy which are pursued, with very different contents and outcomes in terms of their sustainability strategies. All these are important aspects when achieving the main goal of management control in the field of sustainability: to influence the behavior of managers and employees to achieve defined sustainability-related strategies and objectives.

[Sustainable change management](#)

Definition/Description

Over the last three decades, there has been an increased emphasis and drive for sustainability from firms both in the for-profit and nonprofit sectors across the globe. The transition to the sustainability-focused outlook for businesses was initially that of rejection; and more recently, moved to a more recently positive attitude, which considers sustainability as a key strategic organization goal (Sloan et al. 2013). This is due to the realization that sustainability focus is not only good for the organizations and the earth, but it holds additional benefits including economic prosperity, protection of the environment, and social equity (Soyka 2012).

Buchanan et al. (2007) defined sustainability as the process through which novel working methods, enhancements for performance and continuous improvements are kept in place for a time linked to a specific context. More recently, sustainability has been linked with the UN Sustainable Development Goals (UN SDG's); however, this entry will not limit itself to either of the two perspectives. Rather, a convergence of both, which involves the broader context of sustainability is adopted. Teece and Pisano (1994) proposed the theory of dynamic capabilities, which argues that organizations need to deal with a changing context by reviewing, adapting, editing, and continuously improving their routines. There remains a question of how firms can handle this transition to sustainability via routines and practices within their organizations.

Managing change for sustainability therefore involves:

...adapting firms' resources and associated stakeholders to the requirements for sustainability. This involves configuring and allocating resources to the planning (structural), people (staff-related) and process areas of sustainability targets, and ensuring that the change is dynamic (non-static) and clear to all stakeholders.

Introduction

The most challenging task in the transition of sustainability is moving from business as usual to sustainability-oriented goals (Parsons and Cornett 2011). A critical part of this difficulty lies with staff members, who may be motivated at the start of the sustainability drive but the motivation dissipates along the line. Maher et al. (2010) outlined three crucial aspects of managing change for sustainability, namely: structural factors (organizational), staff (people), and process factors. These three areas will be examined, with two additional criteria, identified from the literature for managing change for sustainability.

Structural Issues (Organization)

In managing the change for sustainability, firms need to endeavor to introduce internal structures, which are linked to the organization's vision, strategic goals, and culture (Franz-Balsen and Heinrichs 2007). Kilpatrick (2001) also outlined that institutional structures within a firm or community can facilitate or hinder the change towards sustainability. Thus, organizations are encouraged to provide the needed support structures for the incorporation of sustainability, which could be in the forms of equipment, policies and procedures, communication, and job descriptions. Doing this will allow the system to be easily monitored and improved over time. Sloan et al. (2013) argue that firms with a flatter decision-making structure and less compartmentalized communications make it easier to be proactive in the area of sustainability, especially when managing change.

The change for sustainability will also run smoother with a “sustainability champion,” who will build capacity within the firm (Kilpatrick 2001). In addition, the firm should endeavor to decentralize leadership drive for sustainability to meso-level middle managers, who will then be responsible for managing the change process.

Staffing Issues (Human Resources)

This theme concerns itself with the staff members involved in the transition to sustainability. In the change process to sustainability, organizations need to empower and train staff to be a part of the change process and believe in the change (Parsons and Cornett 2011). Sometimes, the firm may also need to engage external consultants to support the change for sustainability.

Process/Procedural Issues

Kemp et al. (2007) espoused that the process of change for sustainability is never-ending and progressive, as it involves multiple transitions or system innovations. The process in the change for sustainability involves iterations in culture, practices, and operations. The change process must also be measurable in tangible terms, i.e., linked to either sustainability targets, the UN SDGs or other alternative sustainability criteria set within the company or business environment. The process must also continuously improve and not remain static.

Versatility

Gugić (2009) outlined that in order to be able to manage the change to sustainability, firms must be able to adapt quickly within changing and unpredictable conditions in dynamic ecosystems. Thus, versatility is a critical part of managing the change to sustainability as firms need to be able to adapt to the change and be capable of doing in innovative ways, while questioning

the firms’ objectives drive towards sustainability and experiences.

Clarity

Vidović and Bjeliš (2006) outlined the need for clarity in the process of change to sustainability. Unclear goals, high level of uncertainty and insecurity, combined with the perceived lack of adequate support from key stakeholders (e.g., government bodies, expert services) will lead to a lack of clarity in the process. Firms must ensure a high level of clarity in the sustainability goals, targets, and objectives of the organization.

Summary

As firms continue in their drive towards sustainability, the definition presented in this entry outlines the adaptation requirements of firms for sustainability. The definition highlights five (5) critical issues of configuration/adaptation as firms’ transition to sustainability-focused themes, which includes structural issues, staff issues, process issues, versatility/dynamism, and clarity in the targets.

Definition

Despite many academics have highlighted how CSR consists in a set of voluntary behaviors based on social norms and personal beliefs, the last few years have been characterized by the introduction of several forms of regulations in order to sustain the mandatory adoption of socially responsible practices by enterprises. Specifically, these new forms of regulations have regarded different fields such as nonfinancial reporting, GHG emissions, and corporate governance. According to these evidences, mandatory CSR could be defined as *the adoption of socially responsible practices in order to be compliant with the laws even in absence of a real orientation to these topics*.

The Mandatory CSR

During the last few years, the worldwide market has been characterized by an increasing attention paid by stakeholders to socially responsible practices (KPMG, 2017). These new approaches sign a substantial passage from a shareholder orientation to a stakeholder orientation by the managers. However, a large part of these initiatives have been driven from the provisions of a new form of regulation proposed by governments in order to achieve the highest degree of sustainable development. Furthermore, these evolutions have regarded not only the themes related to the environment but also other items such as the diversity and the nonfinancial reporting practices.

Despite the evidences shown above, the scientific debate is characterized by a substantial skepticism about the possibility to adopt socially responsible practices on mandatory basis. In fact, a literature review performed by Dahlsrud (2008) has highlighted the existence of several definitions of CSR based on the voluntariness of these practices. Specifically, the authors denoted how the European Commission (2001) defined CSR as *“a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their*

stakeholders on a voluntary basis.” Furthermore, the WBCSD (1999) proposed a definition of CSR, *“the continuing commitment by business to behave ethically and contribute to economic development while improving the quality of life of the workforce and their families as well as of the local community and society at large.”* However, the recent past has been characterized by the introduction of explicit reference by policy makers and NGOs to a new form of mandatory-based CSR. An example is represented by the Agenda 2030 which required, within the SDGs 12.6, Member States to *“encourage companies, especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle.”* According to this evidence, the debate about the voluntariness of the CSR is characterized by a high degree of conflict between academics.

The Debate About the Effectiveness of Mandatory-Based CSR

The effects related to the adoption of mandatory-based CSR's protocol have been widely explored by academics during the last few years. In particular, the aims of these studies have been related to the possibility to identify more effective paradigms in order to favor the identification of the more adequate rules. In this sense, recently, the debate has been characterized from an increasing contribution by accounting academics (Bebbington and Larrinaga 2014).

One of the main fields of studies about mandatory CSR is represented by the nonfinancial reporting's sector. These fields of studies have been widely analyzed by academics in the last 10 years due to the increasing number of legal provisions about the disclosure of nonfinancial information.

An increasing number of academics have started to analyze the effects related to the Directive 95/2014/EU due to the presence of several controversies about its real effectiveness (La Torre et al. 2018). In fact, contrary to the typical form of

regulation about nonfinancial reporting's regulation, it does not provide some typical requirements as a common reporting standard and a set of common indicators and information about firms' contribution to sustainable development. Furthermore, some preliminary studies performed within the European context have highlighted how firms with previous experience in voluntary nonfinancial reporting typically disclose more information than the late adopters (Leopizzi et al. 2019). Furthermore, other studies have analyzed the mandatory provisions of the integrated report within the South African context in order to be compliant with the King III Code. Specifically, these studies have highlighted how firms could be characterized from a tick box approach not followed by an effective orientation toward sustainability (Ackers and Eccles 2015).

However, mandatory CSR can limit the signaling effects related to the adoption of sustainable practices. An example is represented by nonfinancial reporting practices. As evidenced by Dumay et al. (2015), the proliferation of nonfinancial reports prepared on mandatory basis negatively impacted on stakeholders' ability to evaluate organizations' behaviors. A similar perspective was highlighted by Sheldon and Jenkins (2020) in their research about the marketization of assurance practices. The authors underlined that external assurance made by practitioners on nonfinancial reports is influenced by the lack of independency. Furthermore, a study by Michelon et al. (2019) showed that the probability to found a restatement in nonfinancial reports increases in the presence of assurers' change. In this sense, traditional paradigms developed by academics to analyze socially responsible activities on a voluntary basis require an in-depth revision in order to consider the effects caused by regulations.

Summary

The exigence to achieve the highest degree of SDGs has impacted on the worldwide policies implemented by States. This new exigence has signed the passage from a voluntary-based to a

mandatory-based approach to CSR by the firms. However, the academics have highlighted how the provisions of a rule does not impact on the firms' behaviors. In fact, the preliminary evidences collected about the implementation of new rules have suggested how the early adopters are typically more oriented to these practices. According to this evidence, an effective transition to new paradigms needs both the involvement of States through their internal regulation and the involvement of private sectors. Within this scenario, the academia's contribution will be determinant through the identification of a new form of education inspired by the most virtuous principles about CSR.

[Companies Act of 2013, Section 135, Corporate Social Responsibility Voluntary Guidelines, Corporate Social Responsibility Policy Rules, 2014, Schedule VII](#)

Definition

The Companies Act 2013 is an act of the Parliament of India on Indian company law which regulates incorporation of a company, responsibilities of a company and directors, and dissolution of a company. The 2013 Act is divided into 29 chapters containing 470 sections and has 7 schedules. The Act has replaced The Companies Act 1956. The Act came into force on September 12, 2013. The newly incorporated Act provides more power to the shareholders, emphasizes more on corporate governance, and introduces for the first time Section 135 on CSR. The distinguishing feature of Section 135 is that

it not only makes the reporting of CSR activities mandatory but goes a step further to mandate CSR activities in the first place. India becomes the first country to include provisions of CSR in company law and make CSR expenditure mandatory for corporate based on pre-specified criteria.

History of the Companies Act of 2013 and of Section 135

Since the late 1990s, CSR activities have increasingly gained prominence both among the policy-makers and corporations' stakeholders due to stricter corporate governance and worldwide disclosure norms coming into the forefront. At the policy level, the formal focus on CSR started in India with the issuance of the Corporate Social Responsibility Voluntary Guidelines in 2009 by the Ministry of Corporate Affairs (MCA [2009](#)). These guidelines rolled out by the Ministry of Corporate Affairs in India were developed through an extensive consultative process with the objective of enabling Indian businesses to understand the nuances of responsible business. It was meant for both large and small businesses alike. These guidelines consisted of nine principles which related to ethics and transparency, product life cycle sustainability, employee well-being, stakeholder engagement, human rights, environmental stewardship, responsible policy advocacy, inclusive development, and consumer well-being. However these voluntary guidelines did not appear to have much effect on the Indian firms, and hence CSR activity was by no means common among Indian firms even after the 2009 guidelines. But one good aspect of the Corporate Social Responsibility Voluntary Guidelines issued by the Ministry of Corporate Affairs of India in 2009 was that it culminated in the enactment of Section 135 of the Companies Act 2013 (MCA [2013](#)).

The first time the market learned of a mandatory CSR requirement was on August 6, 2010. They learned about the fact that the government was planning to enact a new provision in the

company law that would require firms above certain thresholds to develop a CSR Policy to ensure that they contributed at least 2% of their annual net profits to CSR. The response of Indian business to this proposal was negative. The Confederation of Indian Industry (a very large trade group) went against such a rule, as did others. They were worried about the mandating behavior of CSR which was previously voluntary in nature. Despite the negative reaction, the draft of the proposed CSR requirement was put forward by the Standing Committee on Finance on September 8, 2010. The draft was silent with respect to penalty for non-compliance, preferring to rely on disclosure of non-compliance as the remedy. By February 10, 2011, MCA planned to accept the Standing Committee on Finance's recommendations on CSR but would rely on a "comply-or-explain" rule as its enforcement mechanism on the 2% spending requirement. The discussion of the mandatory or comply-or-explain rule was officially settled on July 11, 2011. The Companies Bill was placed before the lower house of the Parliament (the Lok Sabha) containing the provision that became Section 135. The Bill sat in the Lok Sabha for some time and was finally enacted by it on December 18, 2012. The Bill then went to the upper house of the Parliament (the Rajya Sabha) and was enacted by it on August 8, 2013. It received the assent of the President of India on August 29, 2013. The Ministry of Corporate Affairs issues rules on what counts as CSR for purposes of the Act on September 20, 2013. These rules were approved on February 27, 2014. The CSR requirement of Section 135 becomes effective for firms satisfying the size-related thresholds from April 1, 2014.

Provisions of Section 135 and Companies (Corporate Social Responsibility Policy) Rules, 2014

Definition of Corporate Social Responsibility
According to Rule 2(1)(c) of the Companies (Corporate Social Responsibility Policy) Rules, 2014,

“Corporate Social Responsibility (CSR)” means and includes but is not limited to:

- (i) Projects or programs relating to activities specified in Schedule VII to the Act; or
- (ii) Projects or programs relating to activities undertaken by the board of directors of a company (Board) according to the recommendations of the CSR Committee of the Board as per declared CSR Policy of the company subject to the condition that such policy will cover subjects specified in Schedule VII of the Act.

Companies to Which CSR Obligations Under Section 135 Apply

There are two aspects to this. According to Section 135(1) read along with Rule 3 of the Companies (Corporate Social Responsibility Policy) Rules, 2014, applicability of CSR obligations can be divided into two parts which is as follows:

- Applicability to Indian companies, i.e., companies registered in India
- Applicability to foreign companies

Applicability of CSR Obligations to Indian Companies

According to Section 135(1), mandatory CSR obligations under Section 135 of the 2013 Act apply to every company having:

- A net worth of 500 crores or more
- A turnover of 1000 crores or more during any financial year
- A net profit of 5 crores or more during any financial year

CSR obligations shall apply to companies covered by Section 135(1) irrespective of their listing status and whether they are public or private. “Any financial year” referred under Sub-section (1) of Section 135 of the Act implies “any of the three preceding financial years.”

Section 2(57) of the 2013 Act defines “net worth” to mean:

The aggregate value of:

- The paid-up share capital
- All reserves created out of the profits
- Security premium account

From the aggregate, value the following shall be deducted:

- Accumulated losses
- Deferred expenditure
- Miscellaneous expenditure not written off

All the above figures taken to compute net worth should be as per the audited balance sheet. The following reserves should not be included for computation of net worth:

- Reserves created out of revaluation of assets
- Reserves created out of write-back of depreciation
- Reserves created out of amalgamation

According to Section 2(91) of the 2013 Act, “turnover” means the aggregate value of realization made by the company during a financial year from the sale, supply, or distribution of goods or services rendered or both.

“Net profit” as per Rule 2(1)(f) means the net profit of a company as per its financial statement prepared in accordance with the applicable provisions of the Act (Sec. 381(1)(a) and Sec. 198 of the Act) but shall not include the following, namely:

- Any profit arising from any overseas branch or branches of the company, whether operated as a separate company or otherwise; and
- Any dividend received from other companies in India, which are covered under and complying with the provisions of section 135 of the Act.

Applicability of CSR Obligations to Foreign Companies

“Foreign company” according to Section 2(42) refers to the following:

- It must be a company or body corporate;
- It must be incorporated outside India;
- It has a place of business in India whether by itself or through an agent physically or through electronic mode and conducts any business activity in India in any other manner.

According to Rule 3(1) of the CSR Rules, a foreign company defined under Section 2(42) having its branch office or project office in India shall comply with Section 135 and the CSR Rules if it fulfills the criteria in Section 135(1). Net worth, turnover, or net profit of a foreign company of the Act shall be computed in accordance with the balance sheet and profit and loss account of such company prepared in accordance with the provisions of Section 198 of the Act and Sec. 381(1) (a) read with Rule 4 of the Companies (Registration of Foreign Companies) Rules, 2014. Rule 4 of the Companies (Registration of Foreign Companies) Rules 2014 deals with accounts of foreign company relating to its Indian business operations prepared in accordance with Schedule III to the Companies Act of 2013.

Companies to Which CSR Obligation Is Not Required

Every company which ceases to be a company as per Sec. 135(1) of the Act for 3 consecutive financial years shall not be required to constitute a CSR committee and comply with the provisions of Sec. 135 till such time it meets the criteria specified in Sub-section (1) of Section 135.

Mandatory CSR Obligations to Be Undertaken by Companies Covered Under Section 135

Companies covered by Section 135(1) are required to comply with the following obligations laid down by Section 135:

- To form a CSR Committee of directors
- To formulate a CSR Policy based on CSR Committee's recommendations
- Duties of the directors
- To undertake activities included in CSR Policy
- To spend at least 2% of net profit on CSR.

- To disclose CSR Policy in board of director's report as well as on the website

CSR Committee

Composition

According to Section 135(1) read along with Rule 5 of the Companies (Corporate Social Responsibility Policy) Rules 2014, the following needs to be noted:

- The CSR Committee shall consist of three or more directors, out of which at least one director shall be an independent director.
- An unlisted public company or a private company covered under Sub-section (1) of Section 135 is not required to appoint an independent director.
- A private company having only two directors on its Board shall constitute its CSR Committee with two such directors.
- With respect to a foreign company covered under these rules, the CSR Committee shall comprise of at least two persons of which one person shall be as specified under clause (d) of Sub-section (1) of Section 380 of the Act and another person shall be nominated by the foreign company.

Role of the CSR Committee

The Section 135(3) of the 2013 Act read along with Rule 5(2) of the Companies (Corporate Social Responsibility Policy) Rules, 2014, provides that the main objective of the CSR Committee shall be to:

- Formulate and recommend to the Board, a Corporate Social Responsibility Policy which shall indicate the activity or activities to be undertaken by the company as specified in Schedule VII.
- Recommend the amount of expenditure to be incurred on the activities
- Monitor the Corporate Social Responsibility Policy of the company from time to time.
- Institute a transparent monitoring mechanism for implementation of the CSR projects or programs or activities undertaken by the company.

CSR Policy

Definition

According to Rule 2(1)(e) of the Companies (Corporate Social Responsibility Policy) Rules, 2014, “CSR Policy” relates to the activities as specified in Schedule VII to the Act and the expenditure thereon, excluding the activities undertaken in the normal course of business carried on by the company.

Contents of CSR Policy

Section 135(3)(a) of the 2013 Act provides that the CSR Committee shall formulate and recommend to the Board a Corporate Social Responsibility Policy which shall indicate the activity or activities to be undertaken by the company as specified in Schedule VII.

Rule 6(1) of the Companies (Corporate Social Responsibility Policy) Rules, 2014 provides that the CSR Policy of the company shall include the following:

- A list of CSR projects/programs which a company plans to undertake during the implementation year, specifying modalities of execution in the areas/sectors chosen and implementation schedules for the same. The activities shall be related to the activities included in Schedule VII to the 2013 Act.
- Monitoring process of such projects or programs.
- The CSR Policy of the company should provide that surplus arising out of the CSR activity will not be part of business profits of a company.

Duties of the Directors

Section 166(2) of the 2013 Act requires a director of a company to act in the best interests of the company, its employees, the shareholders, the community, and the protection of environment. If a director contravenes the provisions of Section 166, such director shall be punishable with fine which shall not be less than 100,000 rupees but which may extend to 500,000 rupees.

Section 135(4) of the 2013 Act provides that the Board of Directors of every company referred to in Section 135(1) shall:

- Approve the CSR Policy for the company after taking into account the recommendations of the CSR Committee
- Disclose contents of CSR Policy in its report (under section 134)
- Place the CSR Policy on its website, if any, in such manner as may be prescribed
- Ensure that the activities included in the CSR Policy of the company are undertaken by the company.
- The Board of every company shall ensure that the company spends, in every financial year, at least 2% of the average net profits of the company made during the three immediately preceding financial years, in pursuance of its Corporate Social Responsibility Policy.
- If the company fails to spend such amount, the Board shall, in its report made under clause 134(3)(o) specify the reasons for not spending the amount.

CSR Activities

Rule 4 and CSR Activities

Rule 4 of the Companies (Corporate Social Responsibility Policy) Rules, 2014, provides the following:

The CSR activities shall be undertaken by the company, as stated in the CSR Policy, as projects or programs or activities (either new or ongoing), excluding activities undertaken in its normal course of business.

- The Board of a company may decide to undertake its CSR activities approved by the CSR Committee, through a registered trust or a registered society or a company established by the company or its holding or subsidiary or associate company under section 8 of the Act or otherwise.
- Such trust, society or company which is not established by the company or its holding or subsidiary or associate company, shall have to

have an established track record of 3 years in undertaking similar programs or projects.

- The company has specified the project or programs to be undertaken through these entities, the modalities of utilization of funds on such projects and programs and the monitoring and reporting mechanism.
- A company may also collaborate with other companies for undertaking projects or programs or CSR activities in such a manner prescribed by the CSR Committees.
- Companies may build CSR capacities of their own personnel as well as those of their Implementing agencies through Institutions with established track records of at least three financial years but such expenditure shall not exceed 5% of total CSR expenditure of the company in one financial year.

Schedule VII

Activities specified in Schedule VII to the 2013 Act specifies activities which companies may include in their CSR Policies. These are activities relating to:

- Eradicating hunger, poverty, and malnutrition; promoting healthcare including preventive healthcare and sanitation including contribution to the Swatch Bharat Kosh set up by the government for promotion of sanitation and making available safe drinking water
- Promoting education, including special education, and employment enhancing vocation skills especially among children, women, elderly, and the differently abled and livelihood enhancement projects
- Promoting gender equality, empowering women, setting up homes and hostels for women and orphans; setting up old age homes, day care centers, and such other facilities for senior citizens and measures for reducing inequalities faced by socially and economically backward groups
- Ensuring environmental sustainability, ecological balance, protection of flora and

fauna, animal welfare, agroforestry, and conservation of natural resources and maintaining quality of soil, air, and water including contribution to the Clean Ganga Fund set up by the Central Government for rejuvenation of river Ganga.

- Protection of national heritage, art, and culture including restoration of buildings and sites of historical importance and works of art; setting up of public libraries; promotion and development of traditional arts and handicrafts
- Measures for the benefit of armed forces veterans, war widows, and their dependents
- Training to promote rural sports, nationally recognized sports, Paralympic sports, and Olympic sports
- Contribution to the Prime Minister's National Relief Fund or any other fund set up by the Central Government for socioeconomic development and relief and welfare of SC/ST/OBC, minorities, and women
- Contributions or funds provided to technology incubators located within academic institutions which are approved by the Central Government.
- Rural development projects.
- Slum area development – the term slum area shall mean any area declared as such by the Central Government or any state government or any other competent authority under any law for the time being in force

Activities Not Included in CSR

- Activities undertaken in normal course of business.
- Activity undertaken outside India.
- CSR projects or programs or activities that benefit only the employees of the company and their families shall not be considered as CSR activities.
- Contribution of any amount directly or indirectly to any political party under section 182 of the Act shall not be considered as CSR activity.
- Activity not covered within schedule VII of the 2013 Act.

- One-off events such as marathons/awards/charitable contribution/advertisement/sponsorships of TV programs/etc. would not qualify as part of CSR expenditure.
- Expenses incurred by companies for the fulfillment of any Act/Statute of regulations (such as Labour Laws, Land Acquisition Act, etc.) would not count as CSR expenditure under the Companies Act.
- Contributions to National Defense Fund will not be counted as CSR spends.

CSR Expenditure

Section 135(5) of the 2013 Act read along with Rule 4 of the Companies (Corporate Social Responsibility Policy) Rules, 2014, provides that the Board of every company to which CSR provisions apply shall ensure that at least 2% of average net profits of the company made during 3 immediately preceding financial years is spent in every financial year on such policy.

“Average net profit” shall be calculated as per Section 198 (refer to Annexure 1). The following gives us an idea about such calculation:

- In case of *companies registered in India*, average net profits will have to be calculated as under:
 - (a) Take net profit as per its financial statements prepared in accordance with the applicable provisions of the Act.
 - (b) Make adjustments required by section 198.
 - (c) Exclude the following from net profits:
 - (i) Any profit arising from any overseas branch or branches of the company, whether operated as a separate company or otherwise; and
 - (ii) Any dividend received from other companies in India, which are covered under and complying with provisions of section 135 of the Act.
 - (d) Calculate net profit for each of the preceding three financial years as per (a) to (c) above, aggregate them and divide by 3.
- In case of *foreign companies* covered by Rule 3, the average net profits will have to be calculated as under:

- (a) Take net profit of such company as per profit and loss account prepared in terms of clause (a) of sub-section (1) of section 381.
- (b) Make adjustments to net profit in (a) above as required by section 198.
- (c) Calculate net profits as per (a) and (b) above for each of the three preceding financial years, aggregate them and divide by 3.

The company shall give preference to the local area and areas around it where it operates, for spending the amount earmarked for Corporate Social Responsibility activities.

Further if the company fails to spend such amount, the Board shall, in its report made under clause (o) of Sub-section (3) of Section 134, specify the reasons for not spending the amount. There is no specific punishment provided for defaulting on CSR spends obligations.

According to Rule 7, CSR expenditure shall include all expenditure including contribution to corpus for projects or programs relating to CSR activities approved by the Board on the recommendation of its CSR Committee but does not include any expenditure on an item not in conformity or not in line with activities which fall within the purview of Schedule VII of the Act (refer to segment 3.4.3). However expenditure incurred by foreign holding company for CSR activities in India will qualify as CSR spend of the Indian subsidiary if the CSR expenditures are routed through Indian subsidiaries and if the Indian subsidiary is required to do so as per Section 135 of the Act.

The surplus arising out of the CSR projects or programs or activities shall not form part of the business profit of a company.

In the case of companies covered under Section 135, amount of expenditure incurred on corporate social responsibility activities is required to be disclosed in notes to accounts. So disclosure shall be on accrual basis. The total expenditure incurred is what is required to be disclosed and not the total payments made. There is no requirement to disclose breakup of CSR expenditure incurred. There is no requirement to disclose the

computation of 2% of “average net profits” worked out in accordance with Section 198. There is no requirement to disclose the shortfall of CSR spends, if any, as against minimum 2% of average net profits and the reasons for such shortfall.

Also in the case of companies covered under Section 135, they are required to disclose the following regarding CSR in annual return in Form No. MGT.7:

- Amount spent by the company during the financial year in pursuance of its Corporate Social Responsibility policy.
- The amount spent as percentage of the average net profits of the company made during the three immediately preceding financial years.

CSR Reporting

Section 134(3)(o) requires that the report by the Board of Directors shall include the details of the policy developed and implemented by the company on corporate social responsibility initiatives taken during the year. If the company fails to spend 2% of average net profits during a financial year, the Board shall, in its report, specify the reasons for not spending the amount.

Rule 8 of the Companies (Corporate Social Responsibility Policy) Rules, 2014, provides the following:

1. The Board’s Report of a company covered under these rules pertaining to a financial year commencing on or after the 1st day of April, 2014 shall include an annual report on CSR containing particulars specified in Annexure.
2. In case of a foreign company, the balance sheet filed under section 381 (1)(b) shall contain an Annexure regarding report on CSR.

If company fails to comply with section 134 as regards CSR disclosures in Board, report:

- It shall be punishable with fine which shall not be less than ₹50,000 but which may extend to ₹25, 00,000; and
- Every officer who is in default shall be punishable with imprisonment for a term which may

extend to 3 years or with fine which shall not be less than ₹50,000 but which may extend to ₹5,00,000, or with both.

Display of CSR Activities on Its Website

Rule 9 of the of The Companies (Accounts) Rules, 2014, provides that the Board of Directors of the company shall, after taking into account the recommendations of CSR Committee, approve the CSR Policy for the company and disclose contents of such policy in its report and the same shall be displayed on the company’s website, if any, as per the particulars specified in the Companies (Corporate Social Responsibility Policy) Rules, 2014 annexure. (Refer to annexure 2).

Future Directions

The new CSR provisions should be looked at as an effort by the government to make the corporate sector play a complementary role in meeting the broader societal goals along with it. Under the new CSR Rules, the flexibility is given to the companies in choosing and monitoring the projects. The key challenge will be to see how the companies promote efficiency and effectiveness in project implementation without the CSR Rules coming into serious conflicts with the primary objective of shareholder value maximization of companies. It is also to be seen to what extent the corporate sector will willingly lend a helping hand to the government in contributing to the inclusive growth of the nation.

Annexures

Annexure 1

See Annexure. 1.

SECTION 198

Calculation of profits

(1) In computing the net profits of a company in any financial year -

(a) Credit shall be given for the sums specified in sub-section (2), and credit shall not be given for those specified in sub-section (3); and

(b) The sums specified in sub-section (4) shall be deducted, and those specified

in sub-section (5) shall not be deducted.

(2) In making the computation aforesaid, credit shall be given for the bounties and Subsidies received from any Government, or any public authority constituted or authorized in this behalf, by any Government, unless and except in so far as the Central Government otherwise directs.

(3) In making the computation aforesaid, credit shall not be given for the following sums, namely:—

(a) Profits, by way of premium on shares or debentures of the company, which are issued or sold by the company;

(b) Profits on sales by the company of forfeited shares;

(c) Profits of a capital nature including profits from the sale of the undertaking or any of the undertakings of the company or of any part thereof;

(d) Profits from the sale of any immovable property or fixed assets of a capital nature comprised in the undertaking or any of the undertakings of the company, unless the business of the company consists, whether wholly or partly, of buying and selling any such property or assets: provided that where the amount for which any fixed asset is sold exceeds the written-down value thereof, credit shall be given for so much of the excess as is not higher than the difference between the original cost of that fixed asset and its written down value;

(e) Any change in carrying amount of an asset or of a liability recognized in equity reserves including surplus in profit and loss account on measurement of the asset or the liability at fair value.

(4) In making the computation aforesaid, the following sums shall be deducted, namely:—

- (a) All the usual working charges;
- (b) Directors' remuneration;
- (c) bonus or commission paid or payable to any member of the company's staff, or to any engineer, technician or person employed or engaged by the company, whether on a whole-time or on a part-time basis;
- (d) Any tax notified by the Central Government as being in the nature of a tax on excess or abnormal profits;
- (e) Any tax on business profits imposed for special reasons or in special circumstances and notified by the Central Government in this behalf;
- (f) Interest on debentures issued by the company;
- (g) Interest on mortgages executed by the company and on loans and advances secured by a charge on its fixed or floating assets;
- (h) Interest on unsecured loans and advances;
- (i) Expenses on repairs, whether to immovable or to movable property, provided the repairs are not of a capital nature;
- (j) Outgoings inclusive of contributions made under section 181;
- (k) Depreciation to the extent specified in section 123;
- (l) The excess of expenditure over income, which had arisen in computing the net profits in accordance with this section in any year which begins at or after the commencement of this Act, in so far as such excess has not been deducted in any subsequent year preceding the year in respect of which the net profits have to be ascertained;
- (m) Any compensation or damages to be paid in virtue of any legal liability including a liability arising from a breach of contract;
- (n) Any sum paid by way of insurance against the risk of meeting any liability such as is referred to in clause (m);
- (o) Debts considered bad and written off or adjusted during the year of account.

(5) In making the computation aforesaid, the following sums shall not be deducted, namely:—

- (a) income-tax and super-tax payable by the company under the Income-tax Act, 1961, or any other tax on the income of the company not falling under clauses (d) and (e) of sub-section (4);

(b) Any compensation, damages or payments made voluntarily, that is to say, otherwise than in virtue of a liability such as is referred to in clause (m) of sub-section (4);

(c) Loss of a capital nature including loss on sale of the undertaking or any of the undertakings of the company or of any part thereof not including any excess of the written-down value of any asset which is sold, discarded, demolished or destroyed over its sale proceeds or its scrap value;

(d) Any change in carrying amount of an asset or of a liability recognized in equity reserves including surplus in profit and loss account on measurement of the asset or the liability at fair value.

Mandatory CSR an Indian Companies Act 2013, Annexure. 1 (continued)

Annexure 2

See Annexure. 2.

FORMAT FOR THE ANNUAL REPORT ON CSR ACTIVITIES TO BE INCLUDED IN THE BOARD'S REPORT

1. A brief outline of the company's CSR policy, including overview of projects or programs proposed to be undertaken and a reference to the web-link to the CSR policy and projects or programs.

2. The Composition of the CSR Committee.

3. Average net profit of the company for last three financial years.

4. Prescribed CSR Expenditure.

5. Details of CSR spent during the financial year:

(a) Total amount to be spent for the financial year;

(b) Amount unspent, if any;

(c) Manner in which the amount spent during the financial year is detailed below:

1	2	3	4	5	6	7	8
Serial No	CSR Project or activity identified	Sector in which the activity is covered	Projects or programmes Local area or specify the state or district where project or programme was undertaken	Amount Outlay	Amount spent on the project or programme	Cumulative Expenditure up to the reporting period	Amount spent direct or through implementing agency
1							
2							
3							
	TOTAL						

*Give details of implementing agency

6. In case the company has failed to spend the two per cent of the average net profit of the last three financial years or any part thereof, the company shall provide the reasons for not spending the amount in its Board report.

7. A responsibility statement of the CSR Committee that the implementation and monitoring of CSR Policy, is in compliance with CSR objectives and Policy of the company.

Definition

Legal and institutional borders, topographical classifications, and resource kinds are used to define marine coastal resources (Athanasiou et al., 2017). The land-and-seawater interface, also known as the land-and-seawater interface, is where these resources may be found. Between the tidal effect of terrestrial landscape and the coastal

ecosystem, they are situated in the ocean and on the seabed. Some resources, on the other hand, can tolerate and flourish in semiterrestrial environments (Castro & Huber, 2007). Abiotic and biotic components coexist in marine and coastal ecosystems (Castro & Huber, 2007). Abiotic characteristics include all nonliving resources, while biotic features include a wide range of live resources that are important to people, such as finfish and shellfish. Fish, shrimp, crabs, lobsters, mollusks, reptiles, aquatic animals, and higher aquatic plants are examples of these. The majority of live marine species are helpful and necessary for human use or consumption.

Introduction

Bioactive chemicals from sponges Varijakzhan et al. (2021) and cosmeceuticals from marine algae are among the goods obtained from marine species (Beetul et al., 2016). Two-thirds of all critical services are produced in the marine and coastal environment. Mangrove trees, for example, operate as a storm buffer, while the ocean helps to regulate climate. Marine resources have traditionally supported people's lives, particularly those in coastal regions, via subsistence fishing, farming, and commerce. However, owing to the cumulative impacts of human pressures and natural calamities, global marine resources are quickly depleting. The over-exploitation of fishing resources and nonliving raw materials is mostly to blame for the observed decrease. Oil pollution, plastic pollution, marine litter, and habitat degradation are all kinds of marine pollution that have a negative influence on many marine species' breeding grounds and nurseries. Climate change, insufficient legal instruments, and coastal erosion all pose dangers to marine and coastal ecosystems. To address these issues, a number of programs and organizations throughout the globe have developed particular strategic approaches. Marine species conservation, geographical safeguarding (where major marine issues are significant), marine and coastland protection, International Union for Conservation of Nature (IUCN)'s marine orientation programs, capacity-building in coastal areas, proper maintenance and conservation of marine resources, and sustainable use of marine biodiversity are some examples.

The marine ecosystem's living components include a wide range of critical living resources for people and other living things. From microscopic microbes to massive fish and animals like whales and sharks, these resources are plentiful. For direct human ingestion, most live species are necessary. Sponge, cosmetics, and other items are made using other marine materials or products. Humans use a large portion of the ocean's resources, either directly or indirectly. To guarantee that the population of these key stocks stays viable at harvestable levels, it is necessary to regulate the pace of exploitation and use of these resources. Despite the great nutritional content of fish, worldwide seafood intake is considered to be low when compared to other meals eaten. Sport fishing, recreational diving, and home aquariums all make use of marine resources, particularly live resources. Marine life resources have been exploited by agricultural enterprises to make fertilizer and animal feed, among other things. Without a doubt, marine resources are necessary for human survival. We examine how marine resources and ecosystems are changing across the globe, as well as the potential and restrictions for managing the marine environment and its resources, safeguarding the coast, and supporting coastal communities. We also consider how to convey the discovered opportunities or obstacles.

Marine and Coastal Resource Types

Coastal resources are classified into renewable (living resources) and nonrenewable (nonliving resources):

Living Resources

Various marine resources (physical and biological entitlements) that are helpful to man are gathered and used straight from the sea. Finfish and shellfish, such as shrimp, crabs, lobsters, mollusks, reptiles, aquatic animals, and higher aquatic plants, are among the many resources now available. Despite the hundreds of different seafood species, just a few marine species are important to fisheries. The principal living resources are over 200 types of fish. Anchovies, sardines,

herrings, and shads are among the world's most abundant plankton-feeding clupeoid fish. After fish, mollusks are the most lucrative group of exploited marine resources. The mollusk harvest is incomplete without cephalopods such as octopuses and squids. Shellfish like lobster, shrimp, and crab are examples of crustaceans. In addition, the coastal regions are home to over 160 species. Mammals play an important role in maintaining a healthy and diversified marine ecology. Seagrass and algal forests, for example, cover a large area (Vale et al., 2018).

Nonliving Resources

Water, fuels, minerals (salts, sand, gravel, oxygen, dissolved nutrients, magnesium, and phosphorus), waves, currents, light (which influences the development and dispersion of life), fuel, and oil are nonliving elements that impact sand activity. Some have never been used, while others are now being fully used. On the shallow continental shelf, gravel and sand may be found up to 40 meters deep. This pure sediment deposit may be employed in the glass, iron, and steel industries. Garnet, Zircon, Rufite, Tourmaline, Illenite, and Sillimanite are among the valuable solid minerals found along the shoreline and in submerged places. The presence of crude oil and gas in the marine environment has been detected. This occurs in the shallow continental platform's thick layer of sedimentary layers, which is close to the surface.

Benefits and Challenges Affecting Coastal Marine Resources

The hard issue of establishing a realistic, systematic method necessary for balancing the costs and benefits of varied human uses of ecosystems is the main problem confronting natural resource management (Lester et al., 2013). Two-thirds of all critical services are produced in the marine and coastal environment. Subsistence fishing, farming, and commerce have all historically relied on marine resources to sustain people's livelihoods. The following are some of the possible advantages for local regions: A significant percentage of the money created will be returned to the

government and the people in the form of royalties and tax refunds; direct or indirect employment creation; revenue created will help the government restore other economic sectors; indirectly supports Indigenous economic activity; and contributes to a well-structured educated labor force. Apart from the advantages listed above, tourism adds to these resources by accounting for a major amount of the Gross domestic product (GDP)s of coastal countries. These resources are also beneficial to the shipping industry, which harvests nonliving raw materials such as gravel, sand, and corals and drills offshore to get sufficient oil and natural gas throughout the globe (Lester et al., 2013).

The world's marine resources are dwindling. Overexploitation, pollution, and habitat damage are all contributing to the decline (Awange & Kiema, 2019; Newton et al., 2012). By-catch of huge fish with low nutritional value leads to the fast decline of marine populations. Approximately two-thirds of commercial marine fisheries are overfished, and many species have been depleted. The degradation of marine environment remains a serious danger to the fishing industry. Coastal waterways such as estuaries and associated conservative regions such as mangroves and seagrass meadows are crucial breeding sites for many marine creatures. Oil spills, sewage in effluents, and toxic chemicals all contribute to the fast loss of marine habitats. Inadequate investment in alternative coastal regions; absence of livelihood initiatives; institutional coordination; monitoring, control, and surveillance (MCS); and illegal, unreported, and unregulated fishing (IUU) catches (Barbier, 2012).

Finally, owing to the negative environmental deterioration of these resources, vital ecosystem services are especially inaccessible and difficult for individuals to investigate. For example, uncontrolled and irresponsible fishing activities reduce fish populations and ruin coral reefs (Awange & Kiema, 2019). Mangrove destruction for household and industrial needs, as well as land reclamation, is unmanageable. Cyclones and other severe natural phenomena, as well as rising sea levels, wave action, and coastal erosion, all have an effect on this deterioration. Toxic compounds are used inappropriately on land to

fertilize crops, resulting in chemical runoff into the marine environment. As a result, inadequate land-based farming techniques limit people's ability to diversify their livelihoods while also protecting marine resources. This circumstance leads to increased food insecurity and precarious livelihoods for small-scale farmers.

Solutions to Issues Affecting the Resources

The 2030 Agenda for Sustainable Development Goal (SDG) 14 aspires to safeguard and sustainably utilize oceans, seas, and marine resources (Neumann et al., 2017). The SDG 2030 Agenda's objective 14 (target 14.1) addresses marine debris and pollution, with a focus on sources from land-based activities. Untreated wastewater (6.3), municipal and other waste management (11.6), environmentally sound management of chemicals and wastes throughout their life cycles (12.4), and overall waste reduction are all addressed in Goals 6, 11, and 12. (12.5). SDG 15 (target 15.1) also involves identifying and managing terrestrial waste sinks, as well as preventing land degradation and biodiversity loss via the conservation and restoration of terrestrial and inland freshwater ecosystems. For example, preserve ecological functioning, species and habitat conservation, or the continuing supply of ecosystem services, as stated in goal 14.2. The relationship between this and conservation status is being contested, as is whether total protection, such as the designation of no-take and no-use zones, offers higher biodiversity returns than managed reserves (Costello & Ballantine, 2015; Edgar et al., 2014).

Some of the international attempts to address these challenges include community livelihoods in coastal areas, coastal planning, coastal erosion, coastal/marine pollution, solid waste management, climate change consequences, and the interaction of freshwater and seaside/marine pollutants (IUCN, 2009). Six types of protected areas are recognized by the International Union for Conservation of Nature (IUCN), and the issue must be handled from both a scientific and policy standpoint. In addition, the critical scale of individual protected areas, the need for site networking, and the unique

biogeophysical characteristics of coastal systems must all be addressed in this argument. All African coastal nations (excluding Eritrea and Libya) are signatories to the United Nations Convention on the Law of the Sea in terms of international regulatory processes (UNCLOS). This legally binding international agreement regulates ocean activities and requires nations to prevent, reduce, and manage pollution in the ocean. The International Convention for the Prevention of Pollution from Ships (MARPOL 73/78); the London Convention and Protocol on Waste Dumping at Sea; and the Conventions on Migratory Species and Biological Diversity are all multilateral environmental treaties with international reach that include provisions to prevent the harmful impact of marine plastic debris and microplastics. PERSGA (the Red Sea and the Gulf of Aden) and the Guinea Current Large Marine Ecosystem (GCLME) are all significant in boosting regional collaboration and coordination among nations that share similar resources along their coasts.

The Guinea Current Major Marine Ecosystem (GCLME), which spans Western Africa from Guinea Bissau to Angola, is rated 28th out of 64 large marine ecosystems worldwide (LMEs). The GCLME is a key hub of marine biodiversity and food production, including some of the most important coastal upwelling subecosystems in the world. Bans or levies on plastic bags are the most frequent governmental policy in Africa right now. Mauritania, an African country, was the first to implement such a plan. After 70 percent of animals perished as a result of plastic intake, this limitation was enacted (Larsen & Venkova, 2017). Senegal, Côte d'Ivoire, Mali, Ghana, Kenya, Ethiopia, Malawi, Mauritius, Zanzibar (Tanzania), and Uganda are among the African countries that have enacted such bans. Both Cameroon and South Africa have imposed taxation. Conserving sea plants, animals, and ecosystems may help to conserve marine biodiversity. Some countries have taken steps in this direction already, and others should do so as well. Overfishing must also be avoided by creating marine reserves or protected zones inside each state's territorial waters, where fishing is prohibited (Druon, 2010). For example, Australia has established the world's biggest reef and marine

reserve network, the Marine Reserve Network (McGuirk, 2012). Belgium, Denmark, Finland, France, Germany, Iceland, Ireland, Luxembourg, the Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, the United Kingdom, Northern Ireland, and the European Union have all signed the North-East Atlantic Marine Environment Convention (Ardron, 2008). Since June 1, 1999, China has stopped fishing in several areas of the Bohai Sea, Yellow Sea, and East China Sea, with the prohibition lasting three and a half months (Cheng et al., 2004). The GCLME demonstration projects are intended to demonstrate how certain activities might result in major changes in the coastal and marine environment, and they include the following: a system for evaluating and managing the ecosystem's fish and fisheries in order to aid recovery and long-term viability; and a data and information management and decision-making system for the area. In Guinea, a new and growing production pattern has emerged. The current LME refers to the amount of life resources it can retain. The mangrove ecology in Nigeria is being restored and preserved.

Summary

Despite various laws, accords, and initiatives aimed at limiting the depletion of marine resources, the rate of depletion is frighteningly fast across the world. Compared to anthropogenic activity, natural disaster depletion must be seen as small. Official activities in coastal and marine areas did not prioritize biodiversity conservation. People and companies might profit from depletion, particularly if they built upstream of the rivers and tributaries.

Market for Corporate Control and CSR

Andrea Venturelli
Dipartimento di Scienze dell'Economia,
Università del Salento, Lecce, Italy

Synonyms

[Strategic CSR](#)

Definition

The relationship between Market for corporate control and CSR is an ethical concept. In fact, the traditional definition about “market for corporate control” analyzes the concept only through a financial lens while the current scenario is characterized by an increasing exigence to include within the M&A strategies the analysis of the social and environmental effects related to the operations. In this sense, an increasing number of managers have started to consider within their investment the possible externalities related to the adoption of socially responsible business models.

The Relationship Between Competitive Advantage and CSR

According to the preliminary definition of Manne (1965), investors could be interested to buy shares of firms with low stock price in order to increase the overall market value through their competencies. However, this paradigm could not be adequate to the current scenario. In fact, during the last years, several authors have highlighted the existence of several intangible assets that impact on firms' market value.

The exigence to analyze this relationship is related to the large number of studies that have shown how the adoption of socially responsible practices impact positively on firms' value. In this sense, the adoption of these practices allows managers to increase the overall value of the firms due to the positive market effects. In this sense, these effects could be related to the original definition proposed by Manne (1965) who describes these kinds of operations in terms of value variations caused by the managers' knowledge. Furthermore, the positive effects related to the adoption of CSR practices represent an effective driver for the institutional investors interested to achieve gain during a short time period.

Regarding this relationship, several authors tried to develop theories useful for the comprehension of the phenomenon. In particular, a theoretical study conducted by Gray et al. (2009) underlined the existence of five different theories

useful to investigate socially responsible behaviors through an accounting lens. However, despite the coexistence of many theories, one of the main paradigms used to assess the relationship between CSR and market for corporate control is represented by Legitimacy theory (Deegan 2002; Guthrie and Parker 1989). According to the Legitimacy theory, the adoption of socially responsible behaviors favors the achievement of reputational benefits useful to gain, repair, and maintain firms' social capital. Thus, it represents a relevant theory within the field of studies about market for corporate control and CSR due to the direct relationship between investors' trust and reputation. Furthermore, the theoretical evidences collected during the last years were confirmed by the effects caused by social and environmental scandals on financial markets (Seele 2017).

Furthermore, the nexus between M&A and CSR could be analyzed from two different perspectives. Specifically, the existence of two different perspectives is related to the several strategic implications related to M&A. In this sense, the adoption of CSR practices could be influenced by external pressures such as the nonfinancial regulation and the voluntary behaviors of the investors. On the one hand, the existence of external pressure about CSR represents a relevant item during the processes of M&A due to the possible compliance risks related to the absence of the law requirement. In this sense, investors could perceive this scenario both as an opportunity and as a limit for the investment. On the other hand, the voluntary adoption of socially responsible practices after an M&A operation could be related to several factors. Specifically, according to prior studies, the adoption of socially responsible practices after an M&A operation is typically related to the exigence to increase the reputation of the companies. Furthermore, the adoption of socially responsible paradigms could favor the achievement of a social license to operate by foreign investors.

The Unethical Behaviors Related to the Competitive Advantage

As highlighted in the previous section, firms are interested to increase their competitive advantage.

The increase of the competitive advantage through the diffusion of CSR's information represents one of the main strategies adopted by the firms during the last years. In fact, the increasing attention paid by stakeholders to the sustainable development has impacted on financial markets.

Specifically, the last years have been characterized by the birth of new consumer categories inspired by the exigence to act ethically. This market phenomenon has regarded several sectors such as tourism, food and beverage, and automotive. Furthermore, the financial sector has been influenced by this market evolution as evidenced by the proliferation of new financial instruments such as the green bonds and the socially responsible investment (SRI).

As evidenced in prior studies, the exigence to appear "green" has favored the adoption of unethical strategies in order to engage with stakeholders. Specifically, several studies have highlighted the negative implications related to the adoption of unethical practices such as the greenwashing, the impression management, and more recently, the SDG-washing.

The aim of these practices consists in the development of false information in order to avoid the risks related to the stakeholders' negative perception about the products or the services provided on the market. However, the achievement of this goal through these methods is characterized by different behaviors. Specifically, the greenwashing consists in the disclosure of false information while the impression management consists in the adoption of narrative strategies such as graphs, images, and percentage to confuse the stakeholders. Finally, the SDG-washing represents a subfield of the greenwashing, and it consists in the disclosure of false information about the contribution to SDGs.

Summary

The achievement of an adequate degree of investments' remuneration still remains one of the main targets for firms' owners. In fact, despite the multidimensional targets that characterize the life cycle of an enterprise, the ownership is typically interested to achieve the highest degree of remuneration. Furthermore, although the recent years

have been characterized by several changes, this phenomenon regards both stockholders and the speculative investors interested to a short run gain. According to this evidence, an increasing number of firms have started to adopt socially responsible practices to increase their competitive advantage. However, the nexus between profit and sustainable development represents a controversial perspective due to the different implication connected to these two practices. In this sense, policy makers and regulators could implement a new form of control in order to evaluate the possible market fraud caused by the adoption of an untruly form of CSR practices to increase firms' market value.

Market-Based Mechanism of Regulation

Andrea Venturelli

Department of Economic Sciences, Università del Salento, Lecce, Italy

Synonyms

[Regulation](#)

Definition

The market-based mechanisms of regulation consist of a set of incentives to sustain the adoption of more sustainable practices by the organizations. In this sense, they represent an alternative form of regulation. The European Union Trading Emissions Scheme represents a typical example of these tools introduced to mitigate the adoption of practices characterized by a high degree of pollution. Furthermore, according to prior studies, an increasing number of Governments have started introducing these forms of regulation to achieve the highest degree of sustainable development.

The Market-Based Mechanism of Regulation

The need to develop a market-based regulation mechanism is based on the criticisms of the

traditional economic model. Private firms act “imperfectly,” and the policymakers need to identify new strategies to reconstitute the market (Stewart, 1991). These phenomena have regarded the firms that operate in controversial sectors characterized by a high degree of pollution or carbon emissions (Fowlie et al., 2016). Moreover, some States have started introducing this form of regulation to encourage firms that operate with the public sector to adopt more ethical and legal practices within their internal organizations (Caputo & Pizzi, 2019).

The adoption of these practices by the States represents a compelling driver to an effective change for firms. As evidenced by academics, the effects related to the provisions of mandatory rules about corporate social responsibility are limited. Specifically, a large part of these studies has highlighted how an effective organizational change does not even follow the provisions of a set of rules about CSR due to personal attitude regarding these practices. Moreover, these studies have shown how firms interested in CSR regulation are typically characterized by a short-term standardization in terms of practices adopted. On the other hand, market incentives like tax reduction, favorable interest rates, advantages in negotiations with public administration will represent more effective driver for firms.

One of the main theoretical reflections about the criticisms related to regulation was Dumay et al. (2015). Building on the recent debate about social and environmental accounting, the authors highlighted that the proliferation of new forms of regulations about corporate social responsibility limited the signaling effects related to the adoption of sustainable behaviors. In this sense, firms interested to signal their orientation toward sustainable development need to integrate within their nonfinancial reports additional information not required by the law. An example of this phenomenon is represented by SDG Reporting, which represents the new frontier of nonfinancial reporting practices (Bebbington & Unerman, 2020). As evidenced by standard setters, organizations voluntarily integrated the SDGs within

their reports (PwC, 2017). In this sense, organizations that operate in context with specific requirements about nonfinancial reporting practices can signal their contribution to the 2030 Agenda. However, the isomorphic approach used by the late adopters suggests that the integration of the SDGs will not be an effective signal (Pizzi et al., 2020).

Regarding the specific cases that have suggested the existence of market-based mechanism of regulation, an increasing number of academics started to discuss this phenomenon through the analysis of specific jurisdictions. An example of the ineffectiveness that characterizes the traditional form of regulation is represented by the King Code III in South Africa, where some firms have adopted a “tick-box” approach to be compliant with the law (Ackers & Eccles, 2015). Furthermore, another example is represented by Directive 95/2014 in Europe who required large firms to disclose their nonfinancial information on a mandatory basis (Venturelli et al., 2019). On this point, prior studies have denoted the existence of a different degree of transparency within the reports and the highest attitude for early adopters to disclose high-quality reports (Leopizzi et al., 2019).

On the other hand, the preliminary results about the introduction of market-based mechanisms of regulation are positive. Specifically, as evidenced before, these studies have typically analyzed the GHG emissions and the interactions with the public sector. The analysis performed on the environmental impacts has highlighted how firms typically reduced their environmental impacts after adopting licenses (Hajjar et al., 2019). Furthermore, other studies have highlighted how firms that have adopted ethical tools to certify their orientation to sustainable paradigms are typically more profitable than others (Ginesti, 2019). In this sense, the effects related to the adoption of these practices are two-fold. The first perspective is related to the highest financial performance connected to market incentives provided by the Governments (e.g., tax reduction, interest rates). The second perspective is related to the increase of competitive advantage caused by the reputational benefit connected to adopting these practices.

Summary

The increasing exigence to reduce the negative externalities related to the unsustainability of the current economic scenario imposed the identification of new strategies for States. During the last years, it was possible to observe the proliferation of new forms of regulation to sustain the mandatory adoption of socially responsible practices. However, prior studies have highlighted the failure of this approach. The preliminary evidence collected by academics regarding these policies has revealed several differences between CSR's activities developed and the overall quality of these practices. According to this evidence, the market-based regulation mechanism represents a strategic driver for an effective transition to a more sustainable business model. In this sense, regulators should consider the introduction of these new forms of soft regulation within their strategies. Thus, the development of quantitative studies by academics will provide policy makers new insights to identify new policies.

Marketing (Ethics of)

Sumona Ghosh

St. Xavier's College, Kolkata, West Bengal, India

Synonyms

Code of conduct in marketing; Decisions about what are right or wrong; Ethical behavior; Marketing morality; Norms and principles of marketing

Definition

Ethics of marketing are the general set of guidelines comprising moral principles and values that need to be followed with respect to operation and regulation of marketing and also during any kind of marketing communication. It focuses on principles and standards that define acceptable marketing

conduct. Ethics of marketing emphasizes on transparent, trustworthy, and responsible personal and organizational marketing policies and actions and exhibits integrity and fairness to consumers and other stakeholders. It can be regarded as a process whereby the grounds of moral judgments and rules of conduct governing marketing decisions and marketing situations are inquired into. Ethics of marketing should be considered from two perspectives – an individual and an organizational perspective. From the individual perspective, values like honesty, fairness, responsibility, and being responsive towards social and environmental issues can guide complex marketing decisions in the context of an organization. From an organizational perspective, organizational value, codes, and training are necessary to make ethical decisions. Ethics of marketing promotes fairness and honesty in all kinds of marketing communication engaged by the companies with all their stakeholders. By following the moral principles and values of marketing, companies can enhance customer interest in products/services, create value for stakeholders, and build strong customer relationships. It helps companies to decide on their new marketing strategies too.

Introduction

In today's business world, the managers must follow moral principles and values in their judgments and daily decision-making processes. The task is not easy since marketing is the visible interface with not only customers but with all other stakeholders. The functional area most closely related to ethical abuse in firms is marketing. Since marketing is a key functional area in the business organization that is responsible for communicating and satisfying customers, it is closest to the public view and, consequently, is subject to considerable societal analysis and scrutiny (Volle 2013; Murphy and Lacznia 1981). Therefore, ethics of marketing becomes absolutely crucial if an organization wants to build strong customer relationships and enhance customer loyalty which in turn will help in building positive reputation and entering new markets.

The Ethics of Marketing

Development of Ethics of Marketing

The historical development of marketing ethics started in the early twentieth century with the antitrust and consumer protection concerns especially with adulterated food products. Frank Chapman Sharp started teaching a course in business ethics at the University of Wisconsin in 1913, and Sharp and Fox (1937) published a textbook on business ethics which was based on the concept of "fair service" and had chapters on commercial coercion, doctrine of caveat emptor, fair pricing, and the ethics of bargaining. One of the first articles that appeared in the *Journal of Marketing* was an article by Charles F. Phillips (1939) entitled "Some Theoretical Considerations Regarding Fair Trade Laws" where ethics was not directly addressed but the impact of resale price maintenance on competition was specified. The era of the 1950s focused on issues such as fair trade, antitrust, advertising, and pricing.

The 1960s saw the growth of ecological problems, such as pollution and the disposal of toxic and nuclear wastes, and witnessed the rise of consumerism. In 1962 President John F. Kennedy delivered a "Special Message on Protecting the Consumer Interest," in which he outlined four basic consumer rights: the right to safety, the right to be informed, the right to choose, and the right to be heard. These came to be known as the Consumer Bill of Rights (Ferrell et al. 2005). During this period of time, the first comprehensive model for ethics in marketing was developed by Robert Bartels (1967). The model showcased the various variables that influenced ethical decision-making, including participants, cultural influencers, role expectations, and the complexity of ethical decision-making. The 1967 Bartels article provided a foundation for empirical research on ethics of marketing that followed in the 1970s. In the 1970s significant research was conducted by Carroll (1975), Bowman (1976), and Ferrell and Mark Weaver (1978) to name a few on ethical decision-making within the context of a marketing organization. Business academics and practitioners acknowledged business ethics as an important field of study. We had researchers emphasizing on

organization culture, co-workers, and ethical decision-making concerning marketing (Ferrell and Gresham 1985; Hunt and Vitell 1986; Hunt et al. 1989). We also had researchers developing normative framework for marketing ethics which emphasizes on the exchange relationship between the firm and its stakeholders, including the right to exist and even prosper in society (Gundlach and Murphy 1993; Dunfee et al. 1999).

In the 2000s, ethics in the world of business became a major issue with mammoth scandals taking the forefront like Enron, WorldCom, Tyco, Sunbeam, and Arthur Andersen. After these scandals, the significance of the ethical issues and the importance of having a relationship based on trust with stakeholders started getting more and more emphasized by many researchers (Murphy et al. 2005). During 2000–2006 the *Journal of Marketing* published no articles with the word ethics in the title, but articles did appear dealing with ethical issues (Klein et al. 2004). There is still a need to continue theoretical development and its empirical testing of ethical decision-making in marketing.

The Importance of Ethics of Marketing

The ethics of marketing has the following advantages to be looked into:

- Customer loyalty – It helps the company to win the trust and loyalty of its customers on the long-term basis as it is the basic human nature to go for those products that are genuine and authentic in nature.
- Long-term gains – There are various long-term gains attached to following moral principles and values in marketing like customer loyalty, high credibility in the market, increased market share, enhanced brand value, higher sales, and elevated revenues.
- Builds credibility – When the company follows the ethics of marketing, it slowly and gradually builds its distinctive niche in the market as a genuine and authentic brand that also results in the factor of credibility building for the company within the industry among its peers, contemporaries, investors, and other stakeholders and also in the minds of the customers as well.

- Displays rich culture – When the company follows the ethics of marketing, the internal environment comprising of the staff and employees is highly motivated and continuously strives to help the management attain the overall business objectives. They take immense pride in working for such a company. This enhances the rich and genuine culture of the firm in the market.
- Attracts talent – It helps the company to attract the talented professionals who wish to get associated with the company.
- Attains financial goals – By following the ethics of marketing, a firm is in a position to attract financial support from the market which in turn will help in launching the new line of products in the market, tap new market locations, and try out innovative marketing and promotion techniques.
- Enhanced brand value – Following the following moral principles and values in marketing results in the enhanced brand value of the firm, making it the most trustworthy and reliable brand in the market.

Factors Affecting Ethical Decision-Making in Marketing

The factors affecting the moral principles and values that need to be followed with respect to operation and regulation of marketing can be divided into the following three components:

- Individual factors – individual factors that affect the ethical decision-making process include personal moral philosophy, stage of moral development, motivation, and other personal factors such as gender, age, and experience. Moral philosophies are the principles or rules that individuals apply in deciding what is right or wrong. Most moral philosophies can be classified as consequentialism, ethical formalism, or justice.
- Organizational relationships – set of values, beliefs, goals, norms, and rituals shared by members or employees of an organization. Ethical climate of an organization focuses specifically on issues of right and wrong.
- Opportunity – set of conditions that limit barriers or provide rewards.

Key Issues and Future Directions

There is an overlap between marketing ethics and business ethics because the basic frameworks that describe ethical decision-making in an organization include decisions that encompass marketing. In every organization, there is an ethical component to business decisions, regardless of whether it is marketing or some other functional area component. Rising customer expectations, changing employee expectations, government legislation, the inclusion of social criteria by investors, and changing business procurement practices are some of the factors that companies need to evaluate to judge whether they are truly practicing ethical and socially responsible marketing. Ethics of marketing remains a complex area to understand, and hence both normative and descriptive understanding will be required to improve upon it globally. The academic community can contribute to the advancement of knowledge in this important area of marketing and help in building an effective ethics program. Businesses need to remain open to learning more and understanding the importance of managing the internal organizational culture with utmost integrity and transparency.

Marketing and CSR

Alessandro Monti
CBS International Business School, Köln,
Germany

Synonyms

[Sustainable marketing](#)

Definition

The change in our society's thinking towards sustainability also means that companies must address the issue if they want to be competitive in the market on a long-term basis. In this context,

measures in CSR and in sustainable marketing are becoming increasingly relevant. The strategic management of companies is responsible for long-term, anticipatory orientation. Due to the relevance of CSR transformation, it has become all the more important to include sustainability in marketing planning and strategy. Therefore, sustainable marketing is defined as follows: It can be assumed that sustainable marketing, as part of the comprehensive environmental management of market-oriented companies, fulfils the task in all phases of the product or value-added life cycle under economic conditions for a lasting reduction or avoidance of harmful environmental impacts beyond legal and social standards (Balderjahn 2013, pp. 39–40). As a result of the impairment of ecosystems by the industrial mass production of products, a rethinking in society has developed and the issue of sustainability in the marketing mix has become increasingly relevant. In order to remain attractive to consumers, companies want to go through a change process to position themselves sustainably. Overall, sustainable marketing should provide an answer to the following question: How can companies make a relevant contribution to solving the socio-ecological problems associated with their products and thus generate added value for customers?

Introduction

Society has changed in the past years and with it the attitude towards the topic of sustainability. Organizations have also undergone a change in recent years, as they have become an important stakeholder in the sustainability debate. Companies want to make the highest possible profit, but in the meantime, they have to answer more and more questions about sustainability issues related to their products, services, or the value chain, from individual citizens, NGOs, or politicians (Brugger 2010, p. 25). Corporate Social Responsibility is a concept that stems from the publication “Social Responsibilities of the Businessman” by Howard Bowen from 1953 (Agudelo et al. 2019, pp. 3–4). Since then, the term has developed further, but until today, there is still no uniform definition of

CSR. The concept describes the interlocking of economic value creation with social/societal and ecological value creation. It therefore offers companies the opportunity to integrate responsibility for society and the environment into their strategic orientation and core business, thereby expanding their potential at all three levels. This way, a company can make its business model sustainable. It is of high relevance to take the trade-off between profit and sustainability towards understanding their synergy effects. Since its origin, the concept of CSR has been reviewed over the years from different perspectives and with different focuses (Agudelo et al. 2019, p. 17).

Consequently, companies must be able, for example, to manufacture their products with the desired quality while earning an appropriate profit and giving sustainability the adequate attention. It is no longer enough for companies to claim that they are committed to sustainability – they must be able to interact with society (Brugger 2010, p. 25). If companies do not pay attention to the issue of sustainability and do not integrate it into their corporate strategy and communicate it clearly, this may lead to a reduction in profits (Brugger 2010, p. 52). The power of companies is also constantly growing, which ultimately increases their responsibility towards society and the environment. This means that multinational companies not only have an impact on the environment through their production activities and the associated externalities, but they can also influence the lifestyles and consumption patterns of society (Brugger 2010, p. 25).

CSR and Its Integration Within Marketing

In order to be able to understand the multitude of implications of Marketing and CSR, an understanding of current sustainability problems in society on the one hand and the needs of consumers on the other hand is required. Sustainable marketing can have a normative, strategic, operative, and transformative phase. The normative aspect includes the corporate culture, which is important for all stakeholders. Both the

stakeholders who operate within the company and those who operate outside are thus shaped by factors such as corporate guidelines, CSR mission statements, and principles (Belz 2006, p. 141). It should be emphasized that the above aspects must be consistent with the definition of the objectives of a company. In addition, the relationship between ecological, social, and economic objectives should be balanced in order to prevent conflicts (Belz 2006, p. 141). The strategic and operational method implies how companies communicate with consumers and which positioning strategies they pursue in the market. The latter comprises three alignment options. First, with regard to the integration of sustainable products in the market, one option may be that social and environmental aspects are of particular importance. For customers, the price and quality of the products are not as relevant as the sustainable factor with which they want to stand out in society. This is particularly interesting for companies that want to address a specific customer group. Option two combines the aspects of the first option of the positioning strategies. Price and quality of the products are just as important as social and environmental factors. This is particularly relevant for larger companies. The final option is essentially that price and quality of the products are more important than social and environmental sustainability factors, which account for only a small proportion of the overall product value. This is of interest to large companies that want to reach a large number of people with their product (Belz 2006, p. 141). The transformative model is used to describe organizations that actively participate in discussions on sustainability issues. This includes discussions with politics and society. This can support a change towards a sustainable market economy. In addition, it is easier for the economy to sell products and services on a sustainable basis if there is support from political and social institutions. Consequently, CSR is important as a link between business, politics, and society, as it enjoys popularity in all three areas. The benefits of sustainable marketing for companies can be illustrated on different levels. Primarily, sales, turnover, and a corresponding profit should be generated.

However, companies operating in the long term also have to deal with the concept of sustainability and CSR. These activities should be communicated to the target groups by making sustainability efforts transparent. In addition to image building, misunderstandings are prevented and accusations such as greenwashing can be avoided. In this context, there is the possibility to exert influence through sustainable communication concepts (Jonker et al. 2010, pp. 195–196). Companies should always prove to be responsible, reliable, trustworthy, and credible in order to create a positive image. If companies act with a sustainable orientation, a combination of CSR, sustainable marketing and transparency should lead to an even better reputation. Accordingly, more sales, turnover and ultimately more profit can be generated. In the context of the opportunities that come with the integration of sustainable products, the idea of CSR makes the economy responsible for maximizing the positive effects of its own value-added processes and minimizing the negative effects. In this way, companies assume the role of being part of society by contributing to the positive development of sustainability.

CSR and Consumption

According to Balderjahn (2013), sustainable consumption awareness describes the “intention of a consumer to consume in a way that takes into account environmental, social and economic aspects of the quality of life” (p. 182). Mirroring the three-pillar model, sustainable consumption awareness has three main categories: the ecological dimension, the economic dimension, and the social dimension. The ecological dimension comprises the components recycling, disposal, packaging, environmental protection/resources, and climate. It describes a consumption that is designed to protect the environment. The economic dimension includes the components of a simple lifestyle and debt-free and collaborative consumption. This dimension refers to an awareness for the long-term economic and personal well-being of the consumer (Sheth et al. 2011, p. 25). The third dimension deals with social

consumption and includes the components of respect for human rights, fair pay and the renunciation of child or forced labor, discrimination, and maltreatment.

Sustainable Marketing and Corporate Performance

So far, there is still no common understanding of how CSR and sustainability measures affect the financial performance of a company. Especially when CSR is equated with philanthropic activities, there is still widespread belief that such measures cost money and can only be implemented as long as the company is in financial health. This attitude often prevents a factual and fact-based examination of the topic, which means that not all economic opportunities are exploited and risks are taken that could have been avoided in the first place. CSR and sustainability measures can thus make a significant contribution to the company's success if implemented. This can be done at different levels: Through risk reduction, cost reduction, better use of opportunities, increase of innovative strength and company reputation as well as by creating new markets and business models (Hockerts 2007).

Historical Development of CSR and Market-Oriented Measures

The development of CSR in companies goes far back in history. It is interesting to highlight which elementary achievements have shaped the definition and progress of CSR (Carroll 1999, p. 269). The industrial revolution in the eighteenth and nineteenth century and the mass industrialization in the early twentieth century were fundamentally important for the development of CSR. Environmental, social, and economic factors were increasingly influenced by the incipient activities of large companies. In the 1950s, CSR, then known as Social Responsibility (SR) (Carroll 1999, p. 270), was regarded as a social obligation of companies. Companies were expected to pursue the SR in the interest of social values and to align

all corporate processes and decisions accordingly. The awareness of managers and entrepreneurs of their commitment to society emerged during this phase and formed the foundation for the following era of CSR.

In the 1960s there was a growing perception that the meaning of CSR had to be defined (Carroll 1999, p. 270). Companies understood during this time that the SR orientation of business decisions could be justified by the fact that in the long term, more profit could be generated and the company was thus compensated for its social orientation (Carroll 1999, p. 271). In the 1970s, the focus of business was on the further development of CSR. There was a strong emphasis on the relationship between economic actors and society and companies aimed to integrate philanthropic approaches. It was at this time that some definitions of CSR emerged, which served to take into account the needs of the public for the benefit of society. Four factors of social performance were in the focus. These included "social responsibility," "social accounting," "social indicators," and "social audit." The 1980s were the decade in which many new and alternative CSR concepts were established and definitions revised. The following are examples. "Business ethics," "public policy," and "stakeholder theory." There was also a new development of ways of assessing CSR in the 1980s. This was done through a revision of the 1954 hierarchy of needs established by Maslow, where the framework of the hierarchy was redefined and adapted. In addition, CSR was linked to financial aspects and the question arose as to whether the companies implementing CSR could also be profitable at the same time. If companies that integrated CSR into their business structures could operate profitably at the same time, this would have been a clear advantage for CSR development (Carroll 1999, pp. 284–286). Other definitions and concepts emerged in the 1990s and culminated to a new CSR paradigm. Corporate citizenship, business ethics, and stakeholder theory were increasingly present in the 1990s. During this period, however, the concept of "corporate social performance" (CSP) proved to be particularly

fundamental to the development of CSR. This model focused on principles, guidelines, and processes (Carroll 1999, pp. 288–289).

The pyramid of CSR was also one of the important bricks in the development of CSR in the 1990s. The pyramid of CSR was based on the economy and, building on this, the legal, ethical, and philanthropic sectors (Carroll 1991, p. 42). Economic responsibility is the fundamental duty of companies to act on the market in order to create value. Ethical responsibility includes the need for a company's moral standards and activities to adapt to the cultural environment. The legal responsibility stands for the obligation that the existence of a company must also be legal and legit (Carroll 1991, pp. 40–43). The purpose of this pyramid was to provide guidance on all issues related to CSR. Companies were required to combine all four categories of CSR in a suitable relationship to each other and integrate them into their business processes. The twenty-first century finally saw the emergence of CSR as it is known today. CSR has changed the way companies think in the twenty-first century. Global problems that used to be irrelevant to business are now being addressed and integrated into business processes. The management and executive levels are aware that they are no longer measured solely by financial and sales performance. Many aspects influence the development of CSR. Some stakeholders, governments, and NGOs believe that the responsibility for future generations with regard to CSR lies in the hands of current leaders and managers. In addition, it would be difficult for companies to achieve long-term positive development without considering CSR. Moreover, studies show that companies achieve worse results if they simply ignore CSR.

CSR and Product Management

When the management of organizations embarks on a reorientation towards sustainable product concepts, this refers first to a sustainable design (El-Halwagi 2017, p. 4). These are competitive products and services with a sustainable basis in processes such as production, logistics, use, and

waste disposal. Products and services are competitive if they contribute to satisfying consumer needs. This enables companies to operate and to assert themselves in the market. If the above-mentioned phases of the product life cycle are not sustainable, using the example of the fashion industry, the following consequences can occur. In the main production process, the production of fibers leads to the pollution of sustainable raw materials. This includes the negative impact on air and water quality. The world trade resulting from globalization is also putting further strains on ecosystems. Global transport routes and worldwide logistics cause air pollution. The implementation of sustainable products and services aims not only at increasing consumer benefits. It should also have a positive impact on ecosystems and society, with a consequent increase in the quality of life of the general public. The levels of sustainable product concepts can also be defined by the following terms: social-ecological product quality, sustainable innovations, sustainability brands, and sustainability-oriented packaging methods (Balderjahn 2013, pp. 173–178).

Sustainable product quality consists of various components. A durable and long-lasting product can be used several times (Balderjahn 2013, p. 179). As few materials as possible should be used, and the number of different materials minimized. This would also make it possible to reduce the general energy consumption. Furthermore, the materials used should be ecological and not lead to any health restrictions and the use of the product should be environmentally friendly and release few emissions. In connection with sustainable products, it is essential that eco-labeling is used. This makes it easy for consumers to differentiate between substitutes (Balderjahn 2013, pp. 179–180). Socially sustainable products include, for example, those that respect human rights in the work process, do not raise health concerns, and implement the rules of fair trade. Through sustainable innovations, there is the possibility to change fundamentally existing products in a way that they have a lasting basis. Alternatively, new products can be designed with a sustainable product core. When goods become more environmentally friendly or socially compatible,

the result will be a sustainable product innovation (Balderjahn 2013, p. 181). This sustainable product innovation can increase the duration of the product life cycle, while old products can be recycled and reused. Production processes can be built following ecological guidelines. This includes the efficient use of energy and input materials. In the process of energy transformation, the use of regenerative energies is also becoming possible (Balderjahn 2013, pp. 182–183). Finally, packaging options for wrapping the core product should follow sustainability-oriented methods. On the one hand, the core function of the packaging, the protection of goods during the transport process, must still be ensured. On the other hand, sustainable alternative packaging should protect the environment by saving resources and recycling. Companies orientate themselves to the requirements of politics and the economy. The business community is particularly interested in minimizing packaging waste due to resource savings and image building. Recycling and reuse are goals that can be achieved through reusable packaging and packaging with a second use (Balderjahn 2013, pp. 184–185).

CSR and Brands

Sustainable brands refer to goods that support the customer in making sustainable purchases through authentic brand promises. Consumers can identify with the brand and differentiate themselves by buying the products. The brand design is accompanied by the use of sustainable certificates, such as eco-labeling. Since not all brands that promise sustainability communicate it transparently, the customer must grant the company a high degree of trust. The use of eco-certificates and eco-labels by the companies is helpful. In this way, the consumer is relieved of uncertainty and the purchasing risk is reduced, thus increasing the demand for the product. Sustainability labels serve the purpose of “signaling” by communicating information to the customer in order to simplify the purchase decision. By integrating sustainability in all the relevant business operations, companies are able to protect their own

brand from scandals. These include, for example, child labor, inhumane working conditions, or causing environmental pollution. Negative reports can quickly destroy the laboriously and cost-intensively built reputation of a brand (Balderjahn 2013, pp. 183–184).

CSR and Pricing

Pricing is the most important profit driver and can be considered as one of the most important toolsets for a successful and profitable company (Simon and Fassnacht 2009, p. 1; Diller 2008, p. 21). A goal-oriented and value-oriented pricing strategy can improve profitability for companies and generate substantial competitive advantages for organizations. A good pricing strategy will extract the individual willingness to pay of customers in an optimal way, e.g., via smart price differentiation techniques. On the other hand, companies that engage in socially responsible and sustainable products and services might have disadvantages regarding their cost position compared to competitors offering products and services without a CSR approach (Simon and von der Gathen 2014, p. 253). However, as indicated by Matute-Vallejo, Bravo, and Pina (2011, pp. 325–326), CSR has a direct effect on price fairness. Companies regarded as socially responsible are perceived to also set fair prices. In addition to that, a low price strategy may not be regarded as attractive by customers if the respective company has acted in an unfriendly environmental way (Choi and Ng 2011, p. 269). It therefore is important that companies that try to incorporate CSR elements in their business are able to extract a higher willingness to pay from their customers – this willingness to pay needs to support a higher price in order to generate profits. Because of this, pricing strategies need to be considered carefully if companies want to take over their responsibilities in a CSR context, balancing at the same time the needs for profitability, shareholder value, and stakeholder orientation. A responsible and sustainable pricing policy aims at supporting and increasing economic welfare in a society. At the

same time, a sustainable and CSR-oriented pricing policy strives to embody the three pillars of sustainability regarding economy, society, and environment (“Triple-Bottom-Line”) beyond legislative commitments and obligations. Aiming just for profitability can become too short sighted in a business world where the need to deliver sustainable, responsible, and fair management decisions becomes ever more important. Because of those powerful effects that pricing can generate, there must be a well-balanced trade-off between the focus on profit, the responsibility for society as well as the environment, and the need for a fair pricing towards customers. These three categories might seem to contrast each other, as the pursuit of the profit goal can contrast efforts in a CSR context. Up to now, the effects of prices and of the pricing process have largely been examined either from the perspective of a company’s view of the customer and his or her contribution regarding profit maximization or cost recovery from the perspective of the customer, comparing the price and the pricing process and putting it into a greater either financial or behavioral context (Wallendorf 2017, p. 59). Price however expands beyond the customer or the company perspective, and is not detached from a context of moral, cultural, and environmental relationships connecting many stakeholders together. In fact, price can be considered as a “moral assessment grounded in social order” that structures the way transactions between market players are handled (Wallendorf 2017, p. 59). According to modern standards, a sustainable pricing can be consistent with the responsibility of corporations towards society and the environment, and does not necessarily contrast the economic interests of the company (Vachani and Smith 2004, p. 118). Fairness specifically in pricing situations and in economic transactions in general is widely perceived as a central element that constitutes the relationship between companies and consumers (Nguyen and Meng 2013, p. 529). Especially the price setting procedure and the pricing mechanism are regarded as important, as consumers will try to determine whether the outcome is consistent, without self-interest and reflects the

interests of all parties involved (Ferguson et al. 2014, p. 219).

CSR and Communication

In order to differentiate themselves from their competitors and satisfy the needs of the market, many companies use advertising that draws attention to sustainable aspects of their products (Delmas and Burbano 2011, p. 64). Sustainability is often promoted by using key words such as “environmentally friendly” or “100% natural,” although these terms are usually ambiguous or even misleading for the consumer. In addition, unsustainable products such as plastic bottles or flights are often advertised with ostensibly sustainable advertising content (Schmuck et al. 2018, p. 127). These are often so-called greenwashing measures. Companies communicate positive sustainable performance even though it is not actually present or even negative in the sustainability rating. The services presented in advertising can concern both the highlighting of a general corporate commitment and the emphasis on the sustainability of products or services (Delmas and Burbano 2011, p. 66).

TerraChoice (2008/2009, quoted after Delmas and Burbano 2011, p. 64) has found that over 95% of the advertising measures they investigated contain at least one of the “Seven Sins of Greenwashing.” These are the sin of hidden compromise, the sin of the lesser of two evils, the sin of lack of proof, the sin of irrelevance, the sin of deception, the sin of inaccuracy, and the sin of false label. TerraChoice defines them as follows (Delmas and Burbano 2011, p. 64): The sin of hidden compromise lies in emphasizing supposedly sustainable aspects of a product without considering that these aspects cannot be considered sustainable from every point of view. It is complemented by the sin of the lesser of two evils. Here, sustainable aspects of the overall product are highlighted without the company addressing or even concealing less sustainable or even highly environmentally harmful aspects. In the sin of lack of evidence, unverifiable claims about sustainability are presented as facts. The sin of irrelevance arises

when positive sustainable aspects of a product are emphasized even though its properties do not stand out positively from those of other products of the same type. This includes, for example, an explicitly stated renunciation of the use of ingredients that are prohibited anyway. The sin of deception refers to false statements about the sustainability of the product. It is closely related to the sin of inaccuracy, where the statements are formulated in a way that is not false but misleading. An example of this are the key words already mentioned, such as “green,” “eco,” and “environmentally friendly.” The incorrect use of labels can also be classified as wrong and fuzzy, which is also called the sin of the wrong label: Companies sometimes use sustainable certificates without actually having acquired them or create their own label that is not generally certified and thus does not provide valid proof of the product’s sustainability.

Greenwashing describes a green corporate image that is communicated to the outside world for purely marketing purposes in order to be perceived positively in the eyes of the consumer in times of increasing awareness of social grievances and environmental problems and to remain competitive. Greenwashing can mean that companies present incomplete or simply false information to the outside world, or subtly green their marketing activities in order to achieve a link between sustainability and their company among consumers (Furlow 2010). It is also important to distinguish between CSR and philanthropy. In contrast to CSR, philanthropy is a purely social value creation without a return on investment or business relevance (Lin-Hi and Blumberg 2018). The key point here is that CSR is characterized by its proximity to the core business and that philanthropic activities have nothing to do with what the company makes money from. A classic example of this is donations to charity. Of course, such activities can also be used as a marketing tool (Lin-Hi and Blumberg 2018). If a company tries to market a social image that does not correspond to reality, this is referred to as “social washing.”

Overall, the risks are limited to the following factors. Customers may perceive the CSR measures as not very authentic by believing that

companies only communicate the application of CSR but do not actually implement it. There is also a risk that the measures for CSR processes will be assessed as not relevant to sustainability. This could result in negative headlines that damage the reputation, customer loyalty and ultimately sales. In addition, the investments of companies in CSR measures would not bring any benefit. On the contrary, in this case the investments would damage value creation and result in lost revenue. It can thus be stated that CSR measures implemented by companies can lead to a high level of interest among the target groups. If companies develop an understanding that they carry a part of the social responsibility, it is likely that this has a positive effect on their image, reputation, and authenticity. This attitude can increase the number of new customers, strengthen the retention of existing customers, and improve the result of word-of-mouth advertising. In this way, a sustainable process implementation can develop a Unique Selling Proposition (USP) for the company that helps to differentiate itself from the competition in the market. The risks arising from the integration of sustainable products can be explained as follows. Companies that practice CSR are accused of hypocrisy and incredibility in the greenwashing discussion. Critics claim that companies act only in their own interest, neglecting the problems that arise for the environment and society. In addition, companies are repeatedly involved in various scandals, both in the economy and in politics. Examples include corruption scandals, cases of bribery of public officials, or evasion of tax payments due.

Marketing to Children Responsibly: Sustainable Marketing

Chahid E. Fourali

London Metropolitan University, London, UK

Synonyms

Social marketing

This topic may be seen through the lenses of three concentric circles covering overlapping dimensions that impact on the social and environmental dimensions that are the subject of this encyclopaedia: first the marketing dimensions, then the social marketing dimensions which include many social issues including the marketing to children issue which constitutes the third dimension. However, this representation may be seen as inaccurate given that some social marketers argue that their field, although significantly influenced by marketing, does also include other influences. Nevertheless, given the significance of the overlaps between the three areas, and as a preliminary to further elaboration on the topic, we will take in turn each of these levels to highlight the similarities and differences.

To start with, let's look at marketing. This is a developing field that has many definitions. If we refer to two well-known definitions, we would have the following:

The three-decade, simple Chartered Institute of Marketing (CIM) definition defined marketing as "The management process of anticipating, identifying and satisfying customer requirements profitably".

Another "definition" focused on the Key Purpose of marketing (Fourali 2008):

To advance the aims of organisations (whether private, public or voluntary) by providing direction, gaining commitment and achieving sustainable results and value through identifying, anticipating and satisfying stakeholder requirements.

Both definitions highlighted the purpose to satisfying requirements, although the second definition had a broader perspective about what constitutes "customers." Whether applied to a general marketing definition or a definition that focuses on the more specialist field of "marketing to children," the above two definitions may be classified as commercial definitions of marketing. This is because they tend to refer to strategies by marketers to ensure an ongoing market and sustainable profit for their products and services. As an example, consider Red Bull strategies for continuously "recruiting" new young audiences to ensure on-going demand despite the fact that the older generation eventually grows out of red bull (e.g., Jobber and Ellis-Chadwick 2013...). Consequently, the field of marketing to children aims to reflect more the concerns of social marketers about the subtle and insidious marketing means used to targeting children to develop habits that may be, on the one hand, self-destructive (e.g., attraction to sugary, tobacco, or alcoholic products) and, on the other, the destructive effects of such businesses on the environment. In terms of effect on the environment, consider the effect of Coke businesses on the issue of availability of water. By Coca Cola's own evaluation, it has been estimated that it took about 70 liters of water to make 1 liter of Coke (MacDonald 2018). Hence, our treatment of this marketing to children topic adopts this two-pronged perspective that focuses on the adverse effect on this group and the environment. Some readers may also find it useful to refer to the entry on social marketing within this Encyclopaedia.

Both commercial and social marketing require a strategic plan to help achieve their results. This is particularly true for social marketing for children to ensure learning and accountability for the investment activities of social marketers. Fourali (2018—development education) argued that not all social initiatives

Marketing to Children Responsibly: Sustainable Marketing, Table 1 Steps of the social marketing process

SM planning steps	Clarification
1. Problem identification	What is the problem and who is raising it (e.g., NGOs, government)?
2. Planning	Gathering info on context, stakeholders, and theory
3. Purpose/mission	Purpose of program (awareness/changing attitudes? Changing lifestyles?)
4. Situation analysis/ market research	Challenges/opportunities (ending with a SWOT)
5. Objectives	Strategic objectives (how do we compete/address challenges/obstacles, etc.)
6. Target groups/ obstacles	Determining the (primary) target group (most vulnerable?) and SMART objectives (what, who, when, and how much)
7. The customer proposition	Clarifying the proposition (benefit of changes vs no changes)
8. Selecting a marketing mix (new or traditional)*	Details of the marketing mix
9. Implementation of the campaign	Implementation of integrated campaign (recruit, test & manage)
10. Resources/partners	Including all available resources/stakeholders (e.g., academics, Gov., NGOs, businesses)
11. Monitoring/ evaluation (process and outcomes)	Identifying a procedure for monitoring results

Adjusted from Fourali (2016a, b)

are equal in demonstrating their effects. One way to ensure effectiveness of SM projects is to adopt a social marketing plan. One of the most detailed SM plans is the one proposed by Fourali (2016) as shown in Table 1 below.

Definition

As argued above, the topic of “marketing responsibly to children” is one of the areas of interests of social marketing. Hence, the

definitions here revisit the differentiation of social marketing from commercial marketing and then focus on the specific areas of marketing to children.

Social marketing purpose, which differentiates it from general, commercial marketing, is primarily to serve society (hence the word “social”) as well as support any initiative that does so (such as looking after the environment). This was reflected in the MSSSB “key purpose definition” over a decade ago:

To apply marketing alongside other concepts and techniques in order to influence individuals, organizations, policy makers, and decision makers to adopt and sustain behavior which improves people’s lives.

More recently,

A “consensus definition” (Lefebvre 2013) has been drawn by several social marketing organizations around the world. The purpose was to have a common basis to help consistency of interpretation and practice. Here is the definition:

Social Marketing seeks to develop and integrate marketing concepts with other approaches to influence behaviours that benefit individuals and communities for the greater social good.

Social Marketing practice is guided by ethical principles. It seeks to integrate research, best practice, theory, audience and partnership insight, to inform the delivery of competition sensitive and segmented social change programmes that are effective, efficient, equitable and sustainable.

(Lefebvre 2013)

SM should also be differentiated from “social media marketing.” Indeed, a simple search on Google about social marketing throws up many entries addressing “social media marketing” (use of digital media for communication purposes). It should also be differentiated from other concepts such as cause-related marketing or social entrepreneurship (Fourali 2016a).

Social marketing is a quickly developing field of study and application. So much so that a new encyclopedia is being designed to meet the needs of social marketers (Fourali and French 2019).

Social marketing to children is about applying the techniques of social marketing to protect

children from irresponsible marketing and help promote and change their behavior to support a healthier lifestyle.

Introduction

For the purpose of clarity, we would refer to the UN definition of a child. According to the UN Convention on the Rights of the Child, a child is everyone under 18 unless, “under the law applicable to the child, majority is attained earlier”. There have been many concerns about unhealthy habits within the young population that allegedly have been induced by irresponsible marketing. Consider obesity, sexually transmitted diseases, and teenage violence to mention just a few. Focusing on just obesity, Professor Anne Johnson linked early learning that influences the future health of the child to their subsequent health:

...we know, from research done by population scientists and epidemiologists that the kids today in our schools who are obese - and a significant fraction of children are leaving school overweight or obese - are already stacking their risks going into the future, in terms of diabetes, heart disease, cancer and so on. Those kids now, they may be 15, 16 but they're going to start getting really sick within 25 years. If you want to think about that long term trajectory, we have to intervene now. (reported by Riddaway 2016. Page: 35).

Such views have been replicated by others (Fourali, children SM), but what makes these findings more significant is that such insidious effects can be avoided. Already in 2005, the RAND research demonstrated that early intervention programs help mitigate the factors that place children at risks of adverse effects of factors in their environment. In particular they demonstrated that 19 out of 21 reviewed initiatives that supported child development between prenatal to kindergarten period had significant positive effects on children (Karoly et al. 2005). Among the areas targeted were academic achievement, behavior, educational progression and attainment, delinquency and crime, and labor market success, among other domains. The authors argued that the key factors that helped the positive results were

better training of care-givers and smaller child-to-staff ratios.

Irrespective of the social and individual benefits, the estimated economic benefits of the interventions generated a return to society ranging from \$1.80 to \$17.07 for each dollar spent on the program. Consequently, such initiatives represent a high yield return investment.

As well as the above-listed benefits that accrued from initiatives undertaken with the young populations, perhaps the health dimension is one of the most popular ones as it tends to attract a lot of media interests. We will review some of the health benefits of social marketing to children.

Diet and Nutrition

Research showed that food promotion affects children's food preferences. Children exposed to unhealthy food promotion tended to lead to poor diets. This was particularly reflected in promotional activities by established global companies such as McDonald or Coke (Cairns 2012). Such effects particularly affect lower income families as they tend to be more loyal to such brands.

Substance Misuse Including Smoking and Alcohol

Although cultural and legal environment may affect differently different groups of people when it comes to substance misuse, it is clear that most users regret having taken up the habit at an early age. Taking smoking as an example, up to 88% of smokers started smoking before the age of 18 (Surgeon General 2012; Hastings and Domegan 2014). However, by the time the smoker reach adulthood, it is very hard to give up the habit because of the nicotine addiction. Of course, such argument can also apply to other substances. Preventative initiatives have repeatedly showed their effectiveness in various types of substance misuses groups. For instance, in smoking, 14 out 21 studies showed significant effects and 7 showed maintained the benefit (Stead et al. 2006). These are very healthy results. However, even if the outcomes showed that a minority group benefited, the overall investment is still worth it because of the economies of scale of such initiatives that may have a significant degree

of reach. Significant effects of preventative measures were also reflected in problem drinkers. However, perhaps one of the most challenging prevention results can be found in drug misuse, where outcomes seemed to lack continuity of effect. Hence, although some benefits were shown in the short term, there was lack of long-term impact. This shows the need for closer analysis of the causes and support of vulnerable groups.

Obesity

Obesity prevention initiatives appear to show a lot of promises. A study reviewed the effect of preventative programs targeting children and adolescents. Determined that between 1999 and 2009, 25 out of 27 initiatives were effective in inducing behavioral change. The studies showed particular benefits from initiatives that adopted benchmark criteria informed by a social marketing plan.

Other Worthwhile Initiatives

A review of initiatives undertaken by the Social Marketing Gateway, where children as well as various significant others were involved, showed several important initiatives with great promise (SMG 2016). The reviewed initiatives included working with mothers to develop healthy family goals, sleeping safely, addressing domestic abuse, and encouraging dental health.

Key Issues

The above highlighted two particular lines of concerns. One is the need for being alert to the adverse effect of commercial initiatives on the younger populations. This group is particularly vulnerable given its lack of awareness about the long-term destructive effect of developing unhealthy habits and their lack of equipment with the write protective skills and attitude to help face the dangers of unbridled commercial marketing communications.

The other “concern” is induced by promising results offered by the social marketing initiatives with children. Such concern is due to the need to act quickly and make use of the learning garnered through the developing social marketing

armamentarium to help minimize deleterious effects of unhealthy environments, in as broad a meaning as possible.

Future Directions

CSR and social marketing have intertwined roles. SM may be seen as one of the tools available to CSR to help achieve its goals but also ensure sustainability of the results since it looks beyond corporate level actors and addresses the various levels of influences to maximize impact. While SM has demonstrated its effectiveness in addressing many social issues (Fourali 2016a), SM for children is a developing field that is also showing its potential in helping vulnerable children in our societies thereby improving social justice.

Social marketing for children is a particularly complex field as it requires taking into account not only the variety of “actors” that affect the behavioral outcomes of children but also requires capitalizing on the latest findings about children’s development and the best conditions that maximize a healthy childhood that should lead to a long and happy life.

This means that social marketers facing the prospect of helping children need to not only develop as much understanding as possible of the internal and external factors that affect them but find ways to work with the various stakeholders that can help address the “competing self-destructive behaviors” that may be offered by primarily commercial initiatives. This also means that social marketers need to be as eclectic as possible in learning about and adopting affective approaches given the meager resources they have to contend with. In this respect, the new initiative for developing the learning from other social marketing initiatives has been recently given a huge boost in the form of a new initiative for developing the very first international encyclopedia for social marketing (Fourali and French 2019). Such an initiative has a huge promise in enabling exchange of effective and efficient method for helping the children of the world be healthier and develop into healthier adults that in turn help create a better world.

G. d'Annunzio University of Chieti-Pescara,
Pescara, Italy

Synonyms

There are no synonyms of the concept because Materiality is always used with a precise and unique meaning. However, there are many expressions that include the term, such as Materiality analysis (see chapter “Sustainability and Materiality Analysis”), Materiality assessment, Materiality matrix, and Materiality thresholds.

Description

Despite its legal origin, since the beginning of the twentieth century, Materiality has become increasingly prominent in Accounting. Since the concept has many facets (Edgley 2014), several definitions of it were coined over time by academics and boards (see the reviews of Bellandi (2017), Chong (2015), and CRD (2016)). Some of these definitions, referenced both in financial and nonfinancial reporting, are presented in this entry. The minimum common denominator is that Materiality defines the information that is useful for users of corporate reports. Indeed, Materiality gives a measure of the estimated effect that an item of information (or its absence) may have on the accuracy or validity of a report. In other words, Materiality identifies what counts in a report for its readers. Less technically, Materiality is a concept related to common sense, as some remind us that “there is no need to be concerned with what is not important or with what does not matter” (Bernstein 1967, p. 87), and if an issue “doesn’t really matter, don’t bother with it. [...] Without such a rule, unwarranted amounts of time would almost certainly be spent on insignificant matters [...]” (Hicks 1964, p. 158). After discussing the evolution of Materiality, this chapter closes with an introduction to the practical application of Materiality carried out through processes and tools dedicated to the definition of companies’ reporting content.

Introduction

Defining Materiality is important because, although the concept is simple to understand when generically expressed, its application becomes highly problematic in absence of a clear definition (Bernstein 1967, p. 88). From a historical perspective, while interest in Materiality first arose in financial reporting (FR) contexts, definitions used in nonfinancial reporting (NFR – see chapter ► “Nonfinancial Disclosure”) contexts – e.g., social responsibility (see chapter

► “Corporate Social Responsibility Reporting”), sustainability (see chapters ► “Sustainable Reporting”, ► “Sustainability Management and Reporting”, and ► “Sustainability Reporting”), and integrated reporting (see chapter ► “Integrated Reporting for Sustainability”) – have gradually spread with the advent of the twenty-first century. Despite the existing definitions of Materiality sharing a focus on the information’s usefulness for decision-making, different reporting contexts (see chapter ► “Reporting”) assign a different scope to the concept.

Within FR contexts, while users need to avoid misleading information, auditors (see chapter ► “Audit”) need to spend the limited time they can spend on each assurance process on matters of importance and substance (Ibidem).

Within NFR contexts, where Materiality has become a staple during the 2000s, the importance of the concept is linked to the following elements: (a) existence of detailed mandatory rules (which is challenging in either case for different reasons, as mandatory reporting can turn Materiality into a checklist of minimum requirements to be met, removing the need to exercise critical thinking in defining what is material, and the absence of mandatory items has the potential to weaken practice precisely due to the voluntary basis of reporting); (b) the level of detail of existing guidance (because principle-based frameworks allow more discretion than rule-based frameworks); and (c) the growing number of potentially material topics and stakeholders’ expectations on access into what is behind the corporate sustainability focus.

As for the literature, since the end of the twentieth century, Accounting scholars have increasingly proposed both research papers on Materiality (see references for a selection) and dedicated literature reviews (e.g., Iskandar and Iselin 1999; Brennan and Gray 2005; Messier et al. 2005; Chong 2015). Most of the studies in NFR contexts deal with Materiality in one or more settings (such as sustainability and integrated reporting). Furthermore, a special attention to the auditing field is also observable (see chapter ► “Auditing and sustainability”), while some isolated – or

almost isolated – foci also emerge, such as environmental events, sector-specific Materiality, stakeholder engagement (see chapter ► “[Stakeholder Engagement](#)”), and small and medium enterprises.

Materiality in Financial Reporting (FR)

Contexts

According to Holmes (1972, p. 46), the concept of Materiality in the American Accounting community was so influenced by its English legal roots that, despite the term being widely used in the American Accounting literature since the beginning of the twentieth century, the need for its definition only arose in the 1930s. Later, interest in the importance of information disclosure (see chapter ► “[Disclosure](#)”) gradually grew so much that, during the second half of the century, both scholars (e.g., Bernstein 1967; Frishkoff 1970; Hicks 1964; Holmes 1972) and professional bodies – e.g., American Accounting Association (AAA 1957); Financial Accounting Standards Board (FASB 1975) – began to publish on the theme, issuing Accounting standards and memoranda dealing with Materiality. Through the latter guidelines, Materiality required preparers to determine whether reporting misstatements or omissions *could* influence economic judgments and decisions of financial reporting users. Somewhat differently, the US Supreme Court spoke “of what *would* influence investors” (<https://supreme.justia.com/cases/federal/us/426/438/>), and the 1999 SEC Bulletin no. 99 stated that “[a] matter is ‘material’ if there is a substantial likelihood that a reasonable person would consider it important” (<http://www.sec.gov/interp/account/sab99.htm>). Regardless of the detail in different wordings, this approach – in accordance with the user theory – implies a Materiality assessment based on magnitude, nature (i.e., context and qualitative aspects), and quantity of the inaccuracies (Gelmini et al. 2015, p. 137; Lai et al. 2017, p. 535).

Over time, guidelines containing definitions of Materiality in FR settings continued to be issued by national (e.g., for the USA, FASB (2010, 2018) and PCAOB 2010) and international (e.g., *International Accounting Standards Board*,

IASB (2010, 2017); *International Auditing and Assurance Standards Board* – IAASB (2009a, b)) standard setters and boards.

Most guidelines on Materiality do not propose numerical thresholds in order to detect if an item is material or not. Over the years, this “principle-based” approach generated a disclosure problem, because financial statements’ preparers faced difficulties in making Materiality judgments aiming to select the information provided, especially when disclosure standards were set to be applied as some sort of checklist. As a result, companies provided both too much irrelevant information and not enough relevant information.

To overcome this problem, IASB has tried to fill the lack of effective guidance on Materiality in IFRS by operating on three different levels.

First, the nonmandatory 2017 Practice Statement entitled *Making Materiality Judgements* (IASB 2017) clarified that requirements in IFRS need only to be applied if their effects are material.

Second, the 2018 Conceptual Framework for Financial Reporting (IASB 2018a) slightly tuned the definition of Materiality (§ 2.11): “Information is material if omitting it or misstating it could influence decisions that the primary users of general purpose financial reports [...] make on the basis of those reports, which provide financial information about a specific reporting entity.”

Third, the 2018 amendments to IAS 1 and IAS 8 (IASB 2018b) clarified the definition of “Material” aligning the existing standards with the Framework. A few changes can be identified by comparing the 2010 and 2018 versions of the description of Materiality: the term “item” becomes “information”, “users” becomes “primary users”, “economic decisions” becomes “decisions”, and the expression “could [...] influence” becomes “could reasonably be expected to influence”.

Materiality in Nonfinancial Reporting (NFR)

Contexts

Regulation of NFR started at the beginning of the twenty-first century. In this period, the increased focus on NFR forced both standard-setting bodies and legal regulators to review and amend both

Materiality as defined in FR contexts and its application. During this evolution, different perspectives emerged because many Materiality definitions and guidelines were provided (see chapter ► “Sustainability Reporting Guidelines”), as the examples in Table 1 show.

When the various perspectives are compared, both commonalities and differences emerge.

As for commonalities, the NFR frameworks share (among them and with the FR frameworks) the notion that matters are material if they are of such relevance and importance that they could substantively influence the assessment of a report’s intended users.

As for differences, the following can be highlighted:

(a) The various Materiality definitions differ in terms of the matters considered to be relevant, i.e.:

- For FR purposes, the nature or extent of an omission or misstatement.
 - For IR purposes, matters that affect or have the potential to affect the organization’s ability to create value over time (see chapter ► “Value Creation”).
 - For sustainability reporting purposes, an organization’s economic, environmental, and social effects and the effect of the legal, commercial, social, environmental, and political context.
- (b) The role of Materiality depends on the type (principle-based or rule-based) and on the focus (narrow or wide range of stakeholders) of the framework considered. To a closer examination, substantially, differences among these frameworks tend just to pivot on the focus on the Materiality principle, as highlighted by La Torre et al. (2018, pp. 606–607). For example:

Materiality, Table 1 Definitions of Materiality in some NFR frameworks

Source	Salient excerpts
AccountAbility: Exposure draft on AA1000 Framework (AccountAbility 1999) AA1000 Guidance note (AccountAbility 2006) AA1000 Accountability Principles Standard (APS) (AccountAbility 2008) AA1000 Accountability Principles (AccountAbility 2018) Reports (see chapter ► “AA1000 Series of Standards, The”): Evans et al. 2006 Murningham 2013 Zadek and Merme 2003	Materiality concerns “the need to include significant information that is likely to affect one or more stakeholder groups and their assessment of the organisation’s social and ethical performance” (AccountAbility 1999, § 2.2.5) “Material issues are those things that could make a major difference to an organisation’s performance. Material information provides the basis for stakeholders and management to make sound judgements about the things that matter to them, and take actions that influence the organisation’s performance” (AccountAbility 2006, p. 7) “Materiality is determining the relevance and significance of an issue to an organisation and its stakeholders. A material issue is an issue that will influence the decisions, actions and performance of an organisation or its stakeholders” (AccountAbility 2008, p. 12) “Materiality relates to identifying and prioritising the most relevant sustainability topics, taking into account the effect each topic has on an organisation and its stakeholders” (AccountAbility 2018, p. 20)
United Nations Conference on Trade and Development – UNCTD: Guidance on Corporate Responsibility Indicators in Annual Reports (UNCTD 2008)	Materiality is among the quality criteria that “should be taken into account in selecting indicators that meet the common needs of a wide range of users of corporate responsibility reporting” (UNCTD 2008, p. 11) “Information is material if its omission or misstatement could influence users’ decisions. Materiality depends on the size of the item or error judged in the particular circumstances of its omission or misstatement. Thus, it provides a threshold or cut-off point rather than being a primary qualitative characteristic which information must have if it is to be useful” (UNCTD 2008, p. 12)

(continued)

Materiality, Table 1 (continued)

Source	Salient excerpts
International Organization for Standardization – ISO: ISO 26000 (ISO 2010) (see chapter ► “ISO 26000 Standard”)	No definition of Materiality. A list of core subjects/issues is provided “[. . .], and it is an individual organization’s responsibility to identify which issues are relevant and significant for the organization to address, through its own considerations and through dialogue with stakeholders” (ISO 2010, p. vi)
Global Reporting Initiative – GRI: Sustainability reporting guidelines (GRI 2006, 2011, 2013a, b, 2016b) (see chapters ► “Global Reporting Initiative” and ► “Global Reporting Initiative”)	Materiality is among the principles to be used in combination with standard disclosures to define the content of reports “At the core of preparing a sustainability report is a focus on the process of identifying material aspects – based, among other factors, on the Materiality Principle. Material aspects are those that reflect the organization’s significant economic, environmental and social impacts; or substantively influence the assessments and decisions of stakeholders” (GRI 2013a, p. 7) “Materiality is the threshold at which aspects become sufficiently important that they should be reported” (GRI 2013b, p. 17)
<i>International Integrated Reporting Council</i> – IIRC: Materiality. Background paper for <IR> (IIRC 2013a) <IR> Framework (IIRC 2013c)	Materiality is one of IR’s guiding principles “[. . .] relevant matters are those which affect or have the potential to affect the organization’s ability to create value over time” (IIRC 2013a, p.1) “A matter is material if it could substantively affect the organization’s ability to create value in the short, medium or long term” (IIRC 2013c, p. 33)
Sustainability Accounting Standards Board – SASB: Conceptual framework (SASB 2013) Implementation guide (SASB 2016)	“In identifying sustainability topics that are likely to be material for companies in a specific industry”, the 2013 SASB’s Conceptual framework follows the definition of materiality adopted by U.S. Securities laws and case law. “According to the U.S. Supreme Court, information is material if there is “a substantial likelihood that the disclosure of the omitted fact would have been viewed by the reasonable investor as having significantly altered the ‘total mix’ of the information made available”” (SASB 2013, p. 9) “SASB standards are a cost-effective way for issuers to communicate their material sustainability impacts to investors in a decision-useful format that satisfies the requirements of Regulation S-K” (SASB 2016, p. 2)

- Even though the 2013 GRI G4 version increased the focus on Materiality, the general GRI approach substantially reshapes downward the Materiality principle at the operative level. Indeed, if the guidelines propose a list of indicators and issues to be reported, “the more of these indicators a company manages to cover, the higher the (perceived) report’s robustness and completeness will be. The problem with this approach is that the indicators may be considered a fixed list to be complied with, with only few adjustments done according to the Materiality principle [. . .]. Inevitably, in following this approach the issue of

- Materiality loses some relevance [. . .]” (Mio 2013, p. 84).
- The IIRC framework is principle-based and “confers a central role to Materiality. The IR “conciseness” is one of the key features stressed by the framework, and to gather a clear and accepted definition of Materiality is, in the IR context, fundamental and much more important than it was for previous standards” (Ibidem).
- (c) Both GRI and SASB (SASB 2013, 2016) adopt an approach to Materiality applied to specific sectors. In this regard, GRI issued dedicated guidelines and publications (GRI 2016a; RobecoSAM & GRI 2015). Such an approach

was strongly suggested by the literature (Eccles et al. 2012) because, as IFAC recalls (2015, p. 4), the process of determining Materiality is directed by several factors including the industry an organization belongs to.

This increased attention paid to NFR, after years of mandatory rules regulating only FR, stimulated the gradual spread of different mandatory forms of NFR all over the world, although with a variety of orientations.

In Europe, a series of EU directives attempted to bridge the gap between financial and nonfinancial information (NFI). At first, Directive 2013/34/EU required nonfinancial key performance indicators among the contents of the management report. It regulated Materiality as a principle. From its perspective, “‘material’ means the status of information where its omission or misstatement could reasonably be expected to influence decisions that users make on the basis of the financial statements of the undertaking” (Directive 2013/34/EU, art. 2.16). However, “the principle of materiality should not affect any national obligation to keep complete records showing business transactions and financial position” (*ivi*, Whereas no. 17).

Subsequently, Directive 2014/95/EU modified Directive 2013/34/EU and introduced additional NFI disclosure requirements for large public interest entities with more than 500 employees, to be included in their management report (Directive 2014/95/EU, Art. 1). Such requirements are closer to IR than to sustainability reporting (Baumüller and Schaffhauser-Linzatti 2018, p. 101). Materiality underpins the whole Directive although the directive does not mention the concept explicitly. Moreover, when companies provide the required NFI, they “[...] may rely on national frameworks, Union-based frameworks such as the Eco-Management and Audit Scheme (EMAS), or international frameworks” (see chapter ► “EMAS: Eco-Management and Audit Scheme”) that are there listed (e.g., ISO 26000, GRI, etc.) “or other recognized international frameworks” (Directive 2014/95/EU, see Whereas no. 9). The list of potential frameworks grew larger as a result

of a Federation of European Accountants’ position paper (FEE 2016) and a European Commission’s Communication (EC 2017).

As a consequence, the European Materiality framework is quite multifaceted and its concrete manifestation depends both on the reporting framework (see chapter ► “Reporting Framework”) selected and the way it is implemented.

From this perspective, a continuous revision of Materiality is deemed among the “necessary ingredients for businesses to generate more positive impact and enhance their societal value” (CRS Europe & GRI 2017, p. 6).

Implementing Materiality

In NFR contexts, Materiality becomes more difficult to apply than in FR contexts. While in FR contexts the application of Materiality often revolves around thresholds of misstatements and omissions, in NFR contexts quantitative thresholds are not easily applicable for many reasons, depending on the specific reporting setting considered (see Lai et al. 2017, p. 535; Mio 2013, p. 81).

For example, in sustainability reporting settings, the definition of Materiality does not always represent a primary problem because the most widespread standards focus on completeness (i.e., they are based on fixed lists of indicators to be complied with in the complex scenario of a wide range of potential consequences and stakeholders) rather than conciseness. On the contrary, in integrated reporting settings, Materiality gains importance because conciseness plays a key role and, as Lai et al. highlight (2017, p. 536), “value-creation” is a vaguer concept than “sustainability impact”.

At the operative level, the most widespread (FR and NFR) guidelines propose different process-based solutions in order to determine what is material for report content purposes (see Table 2).

Moreover, NFR frameworks propose operative tools. The main tools are listed in Table 3.

Furthermore, since the Materiality determination process can also be disclosed as a material issue itself, sometimes the guidelines require

Materiality, Table 2 The process to define report contents according to some FR and NFR guidelines

Guidelines and references	Process phases	Excerpts
IFRS Practice Statement 2 Making Materiality Judgements: §§ 33–65 (IASB 2017)	1. Identify 2. Assess 3. Organise 4. dedicated disclosures (for GRI and IIRC cases, see Bellandi 2017, pp. 316–317).

Summary

Despite its legal origin, Materiality has become increasingly prominent in Accounting during the twentieth century. While interest in Materiality first arose in financial reporting (FR) contexts since the beginning of that century, Materiality in nonfinancial reporting (NFR) contexts (e.g., sustainability and integrated reporting) has gradually spread only with the advent of the twenty-first century. The several boards and associations that issued NFR guidelines proposed different definitions and approaches to Materiality. Materiality is often a guiding principle (AccountAbility, GRI, IIRC), a criterion (UNCTD), or a guiding objective (SASB). Sometimes, a set of expected disclosures (e.g., GRI) or material issues is provided (e.g., ISO),

also with a focus on a specific industry (GRI and SASB). However, although such existing FR and NFR approaches to Materiality share a focus on the information’s usefulness for decision-making, the different reporting contexts each framework belongs to assign a different scope to the concept. Moreover, in NFR contexts, Materiality becomes more difficult to apply than in FR contexts. While in FR contexts the application of Materiality often revolves around thresholds of misstatements and omissions, in NFR contexts quantitative thresholds are not easily applicable for many reasons depending on the specific reporting setting considered. At the operative level, the most widespread FR (e.g., IFRS) and NFR (e.g., AccountAbility, GRI, IIRC) guidelines propose different process-based solutions in order to determine what is material for report content purposes. More in detail, both NFR guidelines and scholarly frameworks generated operative tools such as matrices and maps to be used during the Materiality determination process.

Materiality, Table 3 Materiality-oriented operative tools in some NFR frameworks

Tool name	Source	Type	Description	Purpose
Materiality matrix	GRI sustainability reporting guidelines, Standards and Manual (GRI 2006, 2011, 2013a, b, 2016b)	Cartesian system	X-axis: significance on economic, environmental, and social consequences Y-axis: influence on stakeholder assessments and decisions	To provide a visual representation of issues and their relative priority
Sustainable value matrix	Eccles et al. (2015)	Cartesian system	X-axis: firm's Materiality issue Y-axis: issue's significance for society	To upgrade the materiality matrix because "materiality only has meaning from the perspective of the entity that determines it" (p. 158)
Significance/influence matrix	IIRC's Consultation Draft (IIRC 2013b)	Cartesian system	X-axis: magnitude of a matter's impact on the organization's ability to create value Y-axis: likelihood of occurrence of a matter	To assess the importance of issues
Materiality map	SASB's website: https://materiality.sasb.org/	Double-entry table	Rows: issues, grouped by general categories and five dimensions Columns: industries, grouped by sectors Cells: level of Materiality of an issue	To identify sustainability issues that are likely to affect the financial condition or operating performance of companies within an industry
Five-factor test	SASB 2016 Implementation guide (SASB 2016)	Double-entry table	Rows: issues, grouped by general categories and five dimensions Columns: industries, grouped by sectors Cells: scores (potential risk/opportunity related to a topic)	To assess whether a company's activities related to a SASB topic might reasonably be likely to have a material impact on the financial condition or results of operations, i.e., to select sustainability topics appropriate to the specific operating context

Definition

The increasing awareness about the need to evolve from traditional to sustainable paradigms highlighted the central role covered by Media. The concept “Media CSR Forum” consists of the combination between the words Media, CSR, and Forum. Despite the three words appear independent, their combination underlines one of the main themes of the current scenario. In fact, during the last years, traditional and digital media (e.g., social network, blog) paid specific attention to organizations’ nonfinancial performance. Thus, Media CSR Forum can be defined as the industries and organizations’ media coverage about socially responsible behaviors.

CSR and Media

Reputation is one of the main intangible assets of an organization. Since the nineteenth century, academics paid specific attention about the effects caused by adverse events on financial performance. On the point, the academics agreed about the existence of a negative relationship between market value and corporate scandals (Plec and Pettenger 2012). This relationship was confirmed by several corporate scandals that have characterized the last decade. However, during the last years, academics started to reflect about the positive relationship between the adoption of socially responsible practices and market value, which represents an alternative perspective of analysis (Mittelbach-Hörmanseder et al. 2020; Veltri et al.

2020). On the point, academics agreed about the existence of a positive relationship between the two dynamics. However, contrarily to corporate scandals, communicate positive performance to stakeholders represents an activity characterized by a high degree of complexity. In this sense, a wide number of organizations started to engage with their stakeholders through nonfinancial reports.

Engaging with stakeholders through traditional nonfinancial reports represents an activity characterized by a high degree of complexity caused by the lack of technical knowledge about nonfinancial indicators (Boiral 2013). Similarly to financial reporting practices, several studies underlined stakeholders' difficulty to evaluate the reliability of nonfinancial reports (Muslu et al. 2019). Furthermore, other studies showed that an increasing number of organizations disclose their nonfinancial information through synthetic indicators characterized by a low degree of transparency for nonexpert users. In this sense, mass media cover a central role due to their capability to engage with nonexpert users through a more narrative and informal approach (Lai et al. 2019; Neu et al. 2020).

During the last years, an increasing number of media started to discuss about CSR. In particular, the positive trend was favored both by the quick development of new media and by the integration of CSR within the agenda of media that operate in another sector. In this sense, CSR is considered both by financial media and by generalist media. Furthermore, the CSR's media coverage was favored by the rapid growth that has characterized new digital platforms such as LinkedIn, Twitter, and Facebook (Lodhia et al. 2020; Lovejoy et al. 2012). Thus, contrary to the past, engaging with stakeholders represents an activity characterized by less barriers. An example of this evolutionary pathway is represented by the increasing number of sustainable start-ups founded through crowdfunding campaigns that have benefit from the mediatic attention paid by traditional and digital media (Pizzi et al. 2021). Furthermore, an increasing number of media started to assign on yearly basis awards to certify socially responsible organizations (Cosma et al. 2018).

Summary

The increasing attention paid by stakeholders on sustainable development radically changed corporate communication. The disclosure of nonfinancial information through annual reports does not represent a signal of orientation toward these practices due to their wide adoption on mandatory basis. Building on this preliminary consideration, media represent a strategic driver to communicate nonfinancial performance to stakeholders. In particular, their adoption favors the development of a dialogic communication between organizations and stakeholders. Furthermore, the attention paid by media to sustainable practices could represent a way to achieve reputational benefits. According to this evidence, the relevance of the media on CSR is greater than the past. In this sense, the implementation of communication strategies based on their involvement represents a strategic driver to engage with stakeholders.

Definition

Media ethics is an immensely important notion affecting the breadth and depth of contemporary philosophy, communications, social sciences,

culture, management practice and strategy, public policy, and law. This applies to practitioners, analysts, consultants, and scholars in all those areas of practice, theory, and method. This elaboration shall expand on and conclude with matters shaping the future as a continual present: An extensive commentary on digital media – though more established, *traditional* media will indeed receive due attention first.

It will be seen that it is near impossible to arrive at a single, all-encompassing definition of media ethics. It is however essential to state that its roots and origins are in the ethics of journalism. (They may be traced to the 1920s (Christians 1977) and appear deeply susceptible to societal norms and political economy; in the context of development since the late 1970s, these are defined by neoliberalism.)

At the risk of reducing its inherent intricacy and thus omitting some components, media ethics may be defined by a long sequence of terms as *the ethics and principles of reporting, communicating and otherwise representing facts, truth/s, artefacts, multiple viewpoints, values, experiences and cultures; within the context of human (and beyond) communication, knowledge, memory and insight; by, and through the means ranging from spoken to written word, recorded and stored fixed material documents, procedures and systems; through any decodable channels, forms, formats, styles, languages; networks and devices; public, private and community based; locally, regionally, nationally, internationally, and globally*. (And, as media and entertainment contracts had stipulated since the advent of satellite television: “throughout the solar system and the known Universe, in perpetuity”.)

It needs to be added that regulatory contexts are intrinsically related to media ethics. The impact of this relationship on professional practice, codes of conduct, and sociocultural effects is considerable.

Wilkins and Christians (2009, 2020) have arguably edited the most comprehensive guide to date on the subject of (mass-)media ethics. Rooted in American media ethics, but also providing a cross-cultural, international, global perspective, this near-encyclopedic tome is consulted here.

(Some other texts hereby gain deserved attention: Bertrand (2018) and Christians et al. (2017), selected among a considerable output on this essential subject.) Wilkins and Christians explore the full breadth of the subject through the work of numerous authorities in the field. The structure of the text is systematic and represents the full spectrum of matters to be examined in “traditional” (Emphasis added: the field itself is of relatively recent date; as the “new” [already outdated term] – digital, interactive media comes to dominate life, so the theory transforms and a prefix is required for mass media) mass-media ethics.

As such, it is of considerable use to anyone first exploring this complex and comprehensive matter:

1. *Philosophical [also historical, social, and psychological] foundations*
2. *Practice – ranging from impartiality as a key precursor of [all] media ethics; photojournalism (Most pertinent in the age of deepfakes, addressed below); diversity; advocacy; propaganda and PR; pornography (A taboo subject for many and exceptionally problematic, especially in interactive contexts and the flood of content in digital media; worthy of separate analysis beyond the scope of this entry); violence; infotainment (Author’s reformulation and emphasis added: The actual section deals with inherent tensions between news reporting and entertainment often forming a hybrid and unwieldy blend with considerable ethical concerns arising from its inconsistent character.); neoliberal contexts of art and entertainment*
3. *Justice, transparency, and conflict of interest in contemporary journalism; digital autonomous systems; peace journalism; privacy and the press*
4. *Institutional: Buddhism (Intend no harm, intend to be of benefit: a subtitle of the chapter may offer insight into such selectiveness.); communitarianism; liberal democratic as free expression; corporate media ownership; media in evil circumstances; commonalities and tensions of journalism and other professions; feminist media ethics; [lack of] global media standard, “ecology”*

Though clearly authorial in its aspects, the volume explores all facets logically presented to a reader.

Bertrand’s edited tome takes a somewhat different angle. (“Within that definition, media are so different that ethics cannot be exactly the same for each. The distinction is clear between the printed press and audiovisual media; or between ‘public’ media (under State control) and commercial media and noncommercial private media” (2018: 6).) A quote for some added insight (2018: 7):

Media ethics is a misty zone. And the guides to the area often are philosophers using obscure language and having no experience as practitioners. Or, conversely, they are practitioners with little knowledge of what the thinking has been in the field. (Bertrand’s (2018) classification of subject matter addresses Press Regimes; The Functions of Media; Types of Media; News and Entertainment; The Participants; Market, Law and Ethics; and Morality, Media Ethics and Quality Control)

In the context of the *[lack of] global media standard, ecology* (Returning to Wilkins and Christians (2009)) – it is worth mentioning that (1) there are some noteworthy attempts to address the matter and (2) the ongoing chaotic fluxes of media through digital transformation command a need for international harmonization of regulation. The latter is explored in the final section of this document. The United Nations aims to provide *self-regulation* (See *Net Neutrality* for the nexus of (self-)regulation, freedom of expression, and the global internet) advice on media ethics in practice. Recent examples noted are Haraszti’s, Puddephatt’s, and Ristow’s treatises for UNESCO (In a UNESCO paper, Chiyamwaka (2008) traces the press/media regulation, “fourth estate” to Burke (in his 1774 speech)) (Haraszti 2008; Puddephatt 2011; Ristow 2009). Critics of media self-regulation in the context of the blurring of boundaries between public interest and corporate control – and especially in the context of the unruly actions on digital media frontiers – tend to suggest that self-regulation may not be an effective way of policing the media. Normative approaches, others suggest, are dated in digital contexts (e.g. Osatuyi and Turel 2018). (The sections below will contrast such approaches, e.g., Fourie (2017), with others.) The futurist and

posthuman discourses are at the forefront of such arguments, notably ranging between radical utilitarian and post-neoliberal contexts (e.g., Mauthner 2019; Tusinski Berg 2018), while others remain more critically reserved (e.g., Mai 2016).

Into the Future: The Ethics of Digital Media and Interactive Communications

As interactive technologies continue to evolve at – metaphorically – exponential rates, the onus of proof is increasingly in the court of technology firms, developers, software engineers, and both corporate and public communications in terms of policy, practice, and (self)-regulation. The internet and gaming are the fields which both know no corporate or physical boundaries of geography (aside from rare systems of censorship) nor those of culture making this matter a global task surpassing the jurisdiction of a single UN member state. Transnational agreements, trade blocks and areas, multidisciplinary fields of theory, method, and practice are all called to the task to regulate, implement, and rethink the field of media ethics. The ongoing debates on net neutrality and open internet are pertinent to more current matters such as deepfakes, fake news, dark PR, propaganda, and disinformation and also cyber-bullying and internet-gaming, and/or pornography addiction. Adding to that are “internet crazes” and “dares” such as “the ice bucket challenge” and a more sinister set of precarious or dangerous networked, user-driven entertainment goads starting from “happy slapping” in the early 2000s. Also, the more recent COVID-related internet “challenges” (e.g. Kamil 2020), dark memes, and panic spreading through social networks and federated applications and flash-mobbing and incitement to violence (sexual or otherwise) and to suicide, harm, and self-harm – in convoluted communities of extremists of different and varied persuasions – all of these listed are active through multifarious mobile networks and increasingly personalized devices integrated with everyday life.

Moreover, with no effective means of protecting the minors and other vulnerable

individuals or groups from any such content and communication to date, all of this calls for a clear, focused, enforceable, and enlightened set of strategically defined and implemented policies on local, national, transnational, and global levels involving all stakeholders in the multitude of media, from traditional print/text news and “infotainment” media to the leaders in internet, communications, and gaming technologies. Such policies must be based on consensus in order to operate effectively; protect lives, jobs and livelihoods, and communities, individuals, and vulnerable groups; and enhance not diminish a sense of humane human interaction among the many who participate or are exposed to the multitude of media contents, networks, and devices. For that to happen, a truly comprehensive analysis, formulation, and implementation of such far-reaching policy needs to be based on enlightened and foresightful debates on media ethics. Understanding the impact of media and its fundamental ethics thus requires delving deeper into the core concepts, development, and history of human communication in order to make sense of the full complexity of its intricate, networked, and convoluted nature at the beginning of the third millennium.

Fake news is a reportedly new phenomenon, a novel form of disinformation. Disinformation is an inherent part of human communication: from the spontaneous oral spread of rumors to highly sophisticated propaganda and PR campaigns. However, the scale and scope, richness, and reach of the internet and its constituent interactive digital media have brought a qualitative (and quantitative) change unusually hard to predict or address by existing means. Namely: qualitative, as the internet relates to the transformative character of increasingly multifaceted human-to-human, human-to-machine, and machine-to-machine interaction (qualitative is also the nature of the nuanced variety of platforms and media tools, devices, and channels in use) and quantitative, as the growing numbers and probable combinations, variations, and permutations of such interactions further convolute the already complicated matter of such communications, content formats, and appearances of authenticity. With the 2017 increase of fake news

being reported and identified, especially in relation to the world's most dominant social networking corporation, Newman (2017: 7; Niklewicz 2017) cautions against exaggeration. (Reportedly, only 1% of Facebook users relied on fake news within their newsfeed though the considered impact of such phenomena on the election of 2016 was much reported since.) Nonetheless, the same section of Reuters Institute for the Study of Journalism 2017 report warns of an insightful possible trend: 12% surveyed used social media as their main source of news and around 28% of under 25 s did so, with a particular reliance on television too; 24% in that demographic across 26 countries surveyed (Newman 2017 citing Newman et al. 2016). Should this prove a trend, it would show a qualitative demographic change in the use of social media for news content.

What exacerbates the problem is the exceedingly refined ability of computer software, hardware, and network tools to enable the creation of unexpectedly convincing forgeries. Known as *deepfakes*, such interferences with the original – or still rarer contrivances designed from the outset – members of the public cannot distinguish from genuine audio-visual recordings of humans, animals, objects, and physical events. This has a considerable potential to create further erosive impact on journalism, the believability of news, authenticity of sources and facts, as well as the very reliability of reporting. Among other authors, Ward (n.d./2020) warns of such phenomena (*"Ethics of Images"*). Moreover, and in a broader context, he addresses the fine nuancing of the argument for a new school of thought to match the needs of multiple stakeholders through the means of new, redefined media ethics fit for the ever-emerging interactive communications.

He highlights the fact that such new cognitive analytical models which need to be utilized for media contexts are dictated by ethical problems, practice, and normative issues of news in a set of new media environments: *The immediacy of interactive reporting by citizens able to publish news is irreversibly transforming the sphere of media*. In such a chaotic, revolutionizing media environment, "Professional journalists share the journalistic sphere with tweeters, bloggers, citizen journalists,

and social media users," threatening the survival of journalism yet also creating new means by which journalism may transform such as "non-profit centers of investigative journalism." Identifying new mixed-media landscapes as the blends of blogging, tweeting (This specific brand of narrowcasting may become obsolete as the landscape transforms, but the nature of snappy, immediate, and link/content-rich text is likely to evolve), broadcasting, and writing of articles – by both amateurs and professionals – Ward distinguishes challenges on two principal levels: (1) trustworthiness, accuracy, and their editorialist grounds as contrasted with online news and (2) reporting from nano (Ward refers to "parochial" reporting)- to global levels. *The transformed newsroom*, he continues, would transform vertically and horizontally: vertically, with new layers and types of editors and editorial processes, with varying levels, profiles of news inputters (Not inconceivable to assume that increasingly some journalists – or even many – would no longer be human, i.e., journo-bots: Quach (2017) already reports journalists losing jobs to robots (i.e., AI software/hardware tools)), and types of input, and horizontally, a variety of media, platforms, channels, forms, and formats. (The future model Ward identified in this instance appears to be materializing steadily – see commentary by Quach (2017) and others.)

Beyond Benevolently Commercial: Influence Beyond PR to Online Goading

Social media and the emerging phenomenon of *influencers* deserve increased attention (e.g. Quinn 2016). This is chiefly towards aim of resolving the considerable riddle of arriving at suitably refined all-encompassing regulatory frameworks and addressing the large-scale, far-reaching influence of social media (corporate, technology matters) and influencers (individual agency within the said context).

There are two aspects to this:

One is the sociocultural and economic PR impact of *influencers* – the growing industry, profession, and lucrative sectors/subsectors of interactive networks, social media, and streaming

platforms. Two is the extent of interference of social media with everyday lives of the vulnerable members of the public.

For example, Wellman et al. (2020) formulate *influencers'* ethics of *authenticity to one's true self* and ethics of *authenticity of the brand and destination* (in cases of travel and tourism that they had analyzed), which helps influencers justify their own pecuniary drive. This area though in need of further analysis remains fairly unproblematic.

Those standards would require far greater scrutiny when exploring the borderline cases of influencer behavior such as the notorious YouTuber Logan Paul's (e.g., Rohde 2019) distasteful visit to the Suicide Forest (Also, his entire visit to Japan which was reminiscent of dismissive near-racist attitudes long gone from mainstream media in the West. Arguably, YouTube celebrity *rank is equivalent* to a new mainstream status; this is despite the ubiquitous channel's fragmented form) or the objectionable, safety-threatening TikTok COVID-related public lavatory "challenge" (e.g., Marr 2020; OpIndia 2020; Wray 2020; Ibbetson 2020). Indeed, these may well represent such extremes of online social media *influencer* behavior (An interesting and rather challenging case of PewDiePie aka Felix Kjellberg – a leading influencer in the gaming world and one of YouTube's greatest successes. Despite being consistently accused of racist and antisemitic rhetoric (Romano 2018), the gamer celebrity renewed a high-grossing contract with the Google subsidy in May 2020 (Thier 2020)) which tend to backfire at those emanating such content. (It does appear that common sense prevailed at a time of crisis; no reports of widespread adoption of the TikTok "challenge" had surfaced.) However, subtler and far more pervasive and formidable influence is also recorded and referred to in other cases. There is growing evidence that underregulated activities of marketing and PR efforts of social media influencers may be affecting the most susceptible (More on the subject of vulnerable recipients of social media outlined below) among the population: children (e.g., Craig and Cunningham 2017; Jaakkola 2020).

Further in the context of digital media, some critics (e.g., Fourie 2017) reject the normative

media ethics for the loss of its heuristic value in an environment he sees as very different and far more varied than that of established media. The established normative theory of media ethics he argues was built around journalism. Citing the pervasive nature of new/emerging media landscapes affecting all aspects of human communication, he posits a normative theory of ethical communication not media per se. Drawing on interactivity and network nature of non-"traditional" media (Fourie's emphasis), Fourie places the weight on a remarked shift of the communication *paradigm* from the media user to a media producer. This, presumably as new media, acts as enablers not mediator/editor in a traditional sense of the term. Fourie is not alone in such thinking. For example, in relation to the behavioral impact of social media, Bhatt (2017: 133) states that "the trajectory from cause to effect is ambiguous – *there is no individual directing the show, only computer code.*" Nonetheless, Grimmelmann (2015) does not perceive "code" as a mere inanimate bit of electronic processing tool. Using the examples of Facebook and OkCupid as the insightful opening of his article, he examines the two algorithms' goal-directed ability to influence users' emotions. The following example does not place responsibility on social media as such. Indeed, it may further emphasize the shift toward individual responsibility of users as actors, agents, and (new-)media producers identified by Fourie (and other critics of "traditional" media regulation).

It does, however, indicate how complex and urgent the matter is. This, not least as – as many had pointed out – there are inherent challenges to regulating and policing the online behavior of the many millions of users of the internet and digital media, including social networks. (Reports appear in the mainstream press concerning the challenging role and PTSD impact of the work pressures affecting social media moderators exposed daily to the full spectrum of extreme content.) Excepting dictatorial bans on content and networks, it is exceptionally difficult to pre-empt the impact of such phenomena as described below within a social framework promoting democratic values and freedom of expression (e.g. in Woodhouse 2019).

An overpowering cause for critical change and the adoption of novel thinking and a profoundly transformative approach to digital media regulation may be found in the truly sinister “blue whale challenge.” An online “game” impelling vulnerable children and young adults toward progressive self-harm and suicide had affected victims across the globe, with fatalities reported (Even typing the search engine term “blue whale challenge” leads the user to a paid advertisement for mental health assistance to tackle depression and suicidal thoughts. This may serve as evidence of a socially conscious response on the part of both public and private mental health and online safety-focused stakeholders) (e.g., Narayan et al. 2019; Adeane 2018; Egypt Today 2018; Rossow 2018). In the UK, for example, the duty of care organization Educare published a comprehensive guide aimed for the protection of children and young adults from the menacing online phenomenon mentioned above (Taylor 2018).

It does appear that a systemic solution is required. With the myriad companies and stakeholders involved across the globe, ever-accelerating pace of technological development, and innovation in convoluted communications, the task is evidently requiring cohesive and coordinated approaches. It remains unclear to what extent regulating online environments can be attained globally. It does seem clear that the means of non-interactive media regulation and the logic of traditional media ethics do not appear fit for purpose any longer, as stated by multiple authors, practitioners, and critics. The organizational challenge remains, and addressing it would involve resolving the contradictions across the stakeholder spectrum. Such contradictions consist of those of political, ideological, economic, strategic, and – not least – moral description across the world’s countries, territories, business organizations, social advocacies, and civil society organizations.

Summary

Media ethics is a complex subject that is set to rise in complexity as the media, technologies that support them, and channels of communication,

representation, content distribution, and dissemination evolve in terms of both number and enhanced convolution. The ultimate problematic aspect of contemporary media ethics in practice is policing the internet and its myriad forms. The sole possibility of enforcing a sense of control in such environments is the utilization of information and communications technologies (ICT) and their tracking capabilities to assert total control. This of course is tantamount to censorship and is therefore incompatible with notions of democracy and free speech upheld by many policy-making and governance bodies the world over. On the other hand, many successfully argue for the greater enforcement of accountability on the part of both the disseminator/producer and consumer/user of media content – in social media, often those roles are interchangeable. Therefore, businesses, governments, various stakeholders, and supra-governmental bodies formulating media policies are left with a continuous paradox of balancing freedoms of speech and expression against the liability and responsibility of actors big and small, state-owned or governed, and corporate, entrepreneurial, and individual alike. It appears that the matter can only progress forward with costly and effort-intensive attention to detail not dissimilar from the role of human moderators of social media. From the outset of automated content creation and dissemination, and we may look back at Gutenberg’s press for inspiration, the notions of control and accountability hanged in fine balance. It is arguably the role of civil society with its multiple media stakeholders to keep watch over technological innovation to pre-empt the problematic notions such as deepfakes and viral propaganda campaigns while allowing users and creators, journalists of all description and audiences of any type, their rightful access to information, content, and distribution of it. Therefore, the notion of media ethics strikes at the very heart of early twenty-first-century society.

Medicine and CSR

Ioannis Φ. Panagiotopoulos
Department of Business Administration,
University of the Aegean, Chios, Greece

Abbreviations

CSR	Corporate Social Responsibility
CSV	Creating Shared Value
ISO	International Organization for Standardization
LMIC	Lower Middle-Income Country
PQ	Patient-Perceived Quality of Care
SDGs	Sustainable Development Goals
UHC	Universal Health Coverage
UN	United Nations
WHO	World Health Organization

Synonyms

CSR; CSR in healthcare sector; Health system; Healthcare; Pandemic; Quality of services

Introduction

The literature in corporate social responsibility (CSR) in several specific sectors is pretty much developed. The literature on medicine and CSR is scarce. The joined term medicine and CSR is vague since it could include:

- CSR programs of health-care organizations related to medicine
- CSR programs of health-care organizations not exclusively related to medicine like environmental programs
- CSR programs of any organization, that are related to health of employees and citizens in general

Thus, it is important to underline that by the term medicine and CSR, the first concept is described, in other words it is about the CSR policies of health-care organizations that are closely related with medicine, and possibly with their core activities.

The dipole of medicine and CSR refers to any healthcare organization that provides either health-related services or products indicatively but not exclusively, public, and private hospitals, pharmaceutical companies, clinics, paramedic firms, industries that manufacture high tech medical equipment, rehabilitation centers, biotechnology firms, etc. The healthcare sector involves several professions like doctors, professional nurses, several health allied professions, medical engineers, chemists, biologists, managers of the healthcare organizations, etc.

CSR is described by International Organization for Standardization (ISO) as the concept that calls corporations to handle social, environmental, and economic issues for the benefit of their employees and local communities (Dănescu and Popa 2020). Generally, CSR policies of health-care organizations could include medicine supply facilities, nursing facilities, food supply facilities, ambulance service, medical assistance and diagnostic medical exams, distribution of medicines, etc. (Rahman et al. 2010).

Thus, it is interesting to see the penetration of the concept of CSR in health sector and whether these organizations follow the modern trends in

CSR as other corporations do in various fields or there are lacunae in the design and application of CSR healthcare activities.

The United Nations for Sustainability in Health

The United Nations (UN) offers vague suggestions for different levels of CSR standards ranging from a minimum where “businesses fulfill their legal obligations or, if laws or enforcement are lacking, that they ‘do no harm;’” to a maximum, which is “the active alignment of internal business goals with externally set societal goals (those that support sustainable development)” (United Nations 2015).

In 2015, all the countries in the UN signed the 2030 Agenda for Sustainable Development. It sets out 17 Goals (SDGs), which include 169 targets. These wide-ranging and ambitious goals interconnect. Goal 3 of UN Agenda for 2030 Sustainable Development is about global health. Specifically, goal 3 is to ensure healthy lives and promote well-being for all at all ages. The individual targets are (United Nations 2015):

- *By 2030, reduce the global maternal mortality ratio to less than 70 per 100,000 live births.*
- *By 2030, end preventable deaths of newborns and children under 5 years of age, with all countries aiming to reduce neonatal mortality to at least as low as 12 per 1000 live births and under-5 mortality to at least as low as 25 per 1000 live births.*
- *By 2030, end the epidemics of AIDS, tuberculosis, malaria, and neglected tropical diseases and combat hepatitis, water-borne diseases, and other communicable diseases.*
- *By 2030, reduce by one-third premature mortality from non-communicable diseases through prevention and treatment and promote mental health and well-being.*
- *Strengthen the prevention and treatment of substance abuse, including narcotic drug abuse and harmful use of alcohol.*
- *By 2020, halve the number of global deaths and injuries from road traffic accidents.*
- *By 2030, ensure universal access to sexual and reproductive health-care services, including*

for family planning, information and education, and the integration of reproductive health into national strategies and programs.

- *Achieve universal health coverage, including financial risk protection, access to quality essential healthcare services and access to safe, effective, quality, and affordable essential medicines and vaccines for all.*
- *By 2030, substantially reduce the number of deaths and illnesses from hazardous chemicals and air, water, and soil pollution and contamination.*
- *Strengthen the implementation of the World Health Organization (WHO) Framework Convention on Tobacco Control in all countries as appropriate.*
- *Support the research and development of vaccines and medicines for the communicable and non-communicable diseases that primarily affect developing countries, provide access to affordable essential medicines and vaccines, in accordance with the Doha Declaration on the TRIPS Agreement and Public Health, which affirms the right of developing countries to use to the full provisions in the Agreement of Trade-Related Aspects of Intellectual Property Rights regarding flexibilities to protect public health, and, in particular, provide access to medicines for all.*
- *Substantially increase health financing and the recruitment, development, training, and retention of the health workforce in developing countries, especially in least developed countries and small island developing states.*
- *Strengthen the capacity of all countries, in particular developing countries, for early warning, risk reduction, and management of national and global health risks.*

Corporate Governance in Health System

The major actors in the healthcare sector are public and private hospitals and pharmaceutical firms. Especially pharmaceutical companies have big turnovers and some of them belong in the most successful companies financial wise all over the world. Health-care companies must compete inside a complicated frame with strict regulation,

needs for employees of high expertise, high cost of machinery and technological medical equipment, increased quality demands, and a hefty relation with the community (Hossain et al. 2019).

Health systems' task is the provision of health-care services meaning services that upgrade, retain, or restore the health of people. This task includes the usual care provided by public and private hospitals and clinics, family doctors, other activities like the prevention and control of communicable diseases, health promotion, health workforce planning, improving the social, economic, or environmental conditions in which people live. Health systems should take care the equal approach to these services by all citizens, that these services are responsive to individual needs and vulnerabilities and that they do not impact a high cost on citizens and their families (World Health Organization Europe n.d.-b).

Effective Health System Governance for Universal Health Coverage (UHC)

Leadership and governance should aim to secure effective oversight, coalition-building, regulation, attention to system-design, and accountability. Three main types of stakeholders who interact with each other determine the health system and its governance:

- The state (government organizations and agencies at central and sub-national level)
- The health service providers (different public and private for and not for profit clinical, para-medical, and non-clinical health service providers; unions and other professional associations; networks of care or of services)
- Societies (population representatives, patients' associations, CSOs/NGOs, citizens associations protecting the poor, etc.) who become service users when they interact with health service providers.

In the framework of the Sustainable Development Goals agenda, WHO works to support countries to exercise effective health systems governance, aiming on strengthening the capacity of states to design and apply policies toward the successful completion of the plan UHC by 2030.

This plan in brief targets to make quality health services available and affordable to all citizens of the planet. It includes the full range of necessary, quality health services, from health promotion to prevention, treatment, rehabilitation, and palliative care across the life course (World Health Organization Europe n.d.).

CSR in Healthcare Sector

CSR is described as the final contribution of business to sustainable development which respects the ability of future generations to cover their own needs (Brundtland 1987). CSR policy could be expressed in a wide spectrum of activities which ranges from donations and philanthropy because it is the "right thing to do," to risk management, all the way to creating shared value (CSV) which incorporates CSR in the core of all corporate functions attempting to simultaneously create benefits for the company and society (Droppert and Bennett 2015). This range regarding the conception and execution of CSR policies is well portrayed by the three types of CSR: (a) ethical, when a firm avoids any detrimental action against society, (b) altruistic, when a firm proceeds one step further than ethical CSR by giving resources for environmental and social issues even with a negative financial impact for it, and (c) strategic, when a firm designs a detailed policy that recognizes the importance of stakeholders' satisfaction and finds a way in order CSR to reward all, including the firm itself (Carroll 1991; Jones 1995; Lantos 2011).

Healthcare companies design CSR activities for their employees, local communities, and citizens in the countries where they are active. They fund and consult social projects, target entrepreneurial and social environments, implement awareness campaigns on population health, and invest in health projects. They also design policies for the preservation of environment, the reduction of pollutant emissions, and waste management, which support public health in the long term as SDGs acknowledge (Dănescu and Popa 2020).

Pharmaceutical companies are special cases because their business decisions directly impact

human health, making CSR efforts particularly important. These firms have been criticized for specific behaviors such as setting prohibitively high prices and sluggishness in responding to demands to provide access to life-saving drugs for poor populations (Droppert and Bennett 2015). Recent epidemiological and demographic shifts, notably the HIV/AIDS pandemic, have magnified pressures to actively work to promote societal well-being. Pharmaceutical companies have been critiqued for using CSR to repair compromised reputations or to reverse public beliefs about their commercial endeavors being unethical (Droppert and Bennett 2015).

A list with the main CSR activities of healthcare companies categorized in three main groups is presented below (Droppert and Bennett 2015; Hossain et al. 2019). The groups concern donations, actions for the enhancement of health systems, and several other programs with various content (Table 1).

The motivations behind these CSR programs from healthcare firms are listed in the next table (Coțiu et al. 2014; Droppert and Bennett 2015; Hossain et al. 2019). They are divided in three main categories: (a) motivations that enhance the reputation of the firm, (b) motivations that distinguished the firm among the competitors, and (c) motivations that are relevant to business ethics (Table 2).

Patient satisfaction is tightly connected with various advantages like greater patient involvement and compliance with therapeutical process, high staff morale, positive word of mouth, or a minimization in patients' litigation intent. Participants highly appreciate positive interactions with the medical staff, expect a correct diagnosis and treatment, and seem to be less affected by administrative procedures or accommodation facilities (Coțiu et al. 2014). Thus, there is a statistically significant link between satisfaction and loyalty (Kessler and Mylod 2011).

Medicine and CSR in Coronavirus Era

Several urgent CSR actions have been implemented by corporations worldwide that are beyond the laws

Medicine and CSR, Table 1 CSR types and relevant specific activities by healthcare organizations

Type	Activity
Donation	Differential pricing sales for medicines for resource poor countries Special licensing agreements for medicines for resource poor countries Free medicine supply Paid medical expenses for various rare diseases and very poor families Free nursing for people of very low income and other vulnerable groups Food supply for people of very low income and other vulnerable groups Medical assistance and programs of diagnostic exams for people of very low income, other vulnerable groups, citizens in remote rural areas and remote islands Provision of ambulance
Health systems strengthening	Training of health care workers Improved local manufacturing Increased product distribution capacity Infrastructure investment Supply-chain support Private or informal provider engagement Promoting uptake of health insurance
Miscellaneous	Loan and microfinance programs mHealth ^a initiatives Social marketing Health issue awareness campaigns Advocacy and policy Targeted research and development, specifically to meet developing country health needs or products with no commercial potential International employee placement program Patients' satisfaction survey

^aThe global observatory for eHealth of the World Health Organization defines mHealth as "medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants, and other wireless devices" (WHO n.d.)

for the confrontation of the pandemic aiming to protect their employees and society in general. Healthcare organizations and especially hospitals and pharmaceutical companies have participated in

Medicine and CSR, Table 2 Groups of motivations behind CSR activities of healthcare organizations

Type	Motivations
Reputational benefit	Perception of firm by consumers Perception of firm by potential funders Relationship and trust building with potential partners and stakeholders Employee recruitment, satisfaction, engagement, and innovation Patients' satisfaction Ranking on stock market indices
Competitive advantage	Entering new markets Expanding consumer base Intelligence gathering on new markets Anticipated long-term financial gain Increased cost-effectiveness of interventions and programs in developing countries Improved efficiencies Opportunity for innovations Special access to local government officials and decision making Customer and employee loyalty
Philanthropy and health impact	Obligation as a health care company Improved population health impact Increasing patient access to necessary medications/health services Greater patient involvement and compliance with therapeutical process

these efforts and how it could be different since the protection of individual and public health is their specialization. During the pandemic healthcare companies have implemented CSR programs like the abovementioned with even more intense pace. Additionally, they have proceeded with the swift design and implementation of new CSR programs especially adjusted to the pandemic conditions. As this pandemic has dual nature, both medical and financial due to the vast consequences of the pandemic and the aftermath measures of social distancing to every country of the world, healthcare organizations must support all population against COVID-19, and especially vulnerable groups of

people like unemployed citizens and people in lower middle-income countries (LMIC), which may have not access to COVID-19 vaccines and other personal protection material. Critical CSR is the specific kind of CSR that has been developed under these unprecedented conditions that threat public health and global economy. Critical CSR is a hybrid newly formed type of CSR that consists of a combination of strategic CSR and tactical CSR since in brief it combines the strategic characteristics of the first and the swift response that characterizes the second type (Panagiotopoulos 2021).

The pandemic has severely negatively affected the health care quality as perceived by inpatients, both in COVID and in non-COVID ones, but more intensely in the former. For a health care organization, this knowledge implies a chance for improvement to be better qualified to face the pandemic (Lopez-Picazo et al. 2021). Some researchers have noticed an improvement in the PQ during the pandemic because of the status of high readiness and its declaration, which may be the most influential factor (López-Picazo Ferrer et al. 2021). Other researchers support that notwithstanding the sudden expansion capacity in healthcare services during the COVID-19 pandemic (Panagiotopoulos 2021), this does not implicate that necessarily the PQ has been increased too. The pandemic may has put aside the quality of care under increasing patient loads. A recent study that examined in-hospital mortality of intubated COVID-19 patients in Greece, in relation to total intubated patient load, intensive care unit (ICU) availability, and hospital region indicates that in-hospital mortality of severely ill COVID-19 patients is adversely affected by high patient load even without exceeding capacity, as well as by regional inequalities. This underlines the need for more substantial strengthening of healthcare services, focusing on equity and quality of care besides just expanding capacity (Lytras and Tsiodras 2021).

As healthcare companies have the general know-how to support public health and health systems and at the same time the sector has accumulated big earnings due to the pandemic, these companies as modern corporate citizens must apply critical CSR strategies to protagonists in the global endeavors to tackle the pandemic. A main

target of these critical CSR policies should be equal access to COVID-19 medicines and vaccines for all people worldwide independently of their personal income, and the stabilization of the health system in every country to keep high quality of healthcare for COVID and non-COVID incidents across all regions in every country.

Conclusion

As modern corporations do, companies in the wide range of medicine sector realize a demanding call from civil society to consider themselves as corporate citizens in a changing globalized world, by designing CSR policies that would certify that they do business with a sense of responsibility and duty to society. Thus, healthcare organizations are expanding and/or reforming their CSR policies in their organizations. CSR may vary among companies of different type inside the wide healthcare field. Such differences are relevant to internal conditions concerning the organization like CSR comprehension, corporate structures for supporting CSR, on-going CSR programs, motivations for CSR, assessment of CSR, recording of benefits to stakeholders and the company itself (Droppert and Bennett 2015), and external conditions like local standard of living, legal frame, corporate tax regulations, etc.

CSR is a modern issue that occupies corporations, and thus there is an evolving comprehension of CSR within organizations. A lot of them concerning their internal and external position regarding CSR could characterize themselves in a transition phase. Sometimes, competition provides good examples of CSR practices and a real way for a company to examine and verify possible benefits from CSR policies back to the organization (Droppert and Bennett 2015).

Some companies consider that philanthropy should be wholly benevolent whereas CSR aims to shape financially sustainable models that can be mutually beneficial to the firms and the stakeholders (Droppert and Bennett 2015). In terms of CSR strategy, firms are at different points on a spectrum ranging from philanthropic donations to integrated systemic shared value business (CSV)

models where firms produce societal value and economic value for them or in other words they are crossing from philanthropic to commercial and what lies between (Droppert and Bennett 2015). Patient satisfaction may be one of the desired outcomes of healthcare information sourced from specialized CSR surveys and patient satisfaction should be as indispensable to assessments of quality and already applied CSR programs as to the improvement of existing programs and the planning and implementation of future CSR activities.

Summary

The experience of pandemic has underpinned the value of healthcare organizations and CSR. Especially, the combination of the two has contributed a lot to humanity to tackle the pandemic and its consequences in social, physical, mental, emotional, organizational, and financial level. Healthcare organizations apply a variety of CSR programs that are categorized into three main types: a) donations, b) actions for the enhancement of health systems, and c) several other programs with various content. Proportionally, there are detected several incentives for these CSR policies which could be listed in three main categories: a) motivations that enhance the reputation of the firm, b) motivations that distinguished the firm among the competitors, and c) motivations that are relevant to business ethics. It is important for healthcare organizations to deepen their understanding of CSR and sustainability in general in order to transform themselves in modern organization of twenty-first century which can take care of humans and support them multidimensionally even during future pandemics.

M&A

Description

Mergers and acquisitions (abbreviation: M&A) are company transactions in which the ownership of companies, specific operating units, or other business organizations is transferred to or combined with other entities. M&A transactions are among the most visible manifestations of strategy at the corporate level. With a single transaction, the strategic course of the organizations involved can be altered permanently, and its size changed dramatically (Schweizer 2002).

As part of the strategic management of companies and other organizations, M&A transactions can allow organizations to grow, to improve their competitive position, or to transform the nature of their business by giving organizations immediate

access to technologies, products, distribution channels, or personnel (Schweizer 2002). M&A transactions are not a rare phenomenon. Since 2000, more than 790,000 M&A transactions have been announced worldwide, cumulating to a known value of over 57 trillion USD (Institute for Mergers, Acquisitions and Alliances 2021). Economic, regulatory, or technological shocks, as well as high stock market evaluations, can lead to so-called merger waves, a clustering of M&A transactions at the aggregate level (Harford 2005).

Introduction

Although the terms “merger” and “acquisition” do not describe the same thing, the growing literature in this field suggests that they are comparable in nature and typically have the same or very similar impacts on companies (Schweiger et al. 1987). Therefore, the terms “merger” and “acquisition” are often used interchangeably.

In a more technical sense, “acquisition” refers to any transfer of ownership. In contrast, a “merger” refers to a transfer of ownership in which one entity legally dissolves into another or both entities merge into a third entity created especially for this purpose (Lajoux 1998). Often, the term “merger” is also used to mean the combination of two companies of substantially equal size, while the term “acquisition” is used to indicate the combination of a large company with a smaller one (Schweizer 2002).

Types of M&a

Even though the terms “merger” and “acquisition” are often used interchangeably, there exist significant differences between these two types of company transactions (Schweizer 2002). Mace and Montgomery Jr. (1962) described and analyzed an interesting phenomenon in this context: When talking with executives of the target company, management representatives of the acquiring company often refer to a “merger” of the two companies, even though it is implied and apparent

that their own company plans to acquire the other. But when discussing the transaction with their board of directors, the acquiring company’s management representatives usually talk about an “acquisition.” This phenomenon has also been observed in the case of the DaimlerChrysler merger, one of the most famous M&A transactions ever. In the words of Mace and Montgomery Jr. (1962):

There seemed to be an inoffensive quality in the word ‘merge’ not found in the word acquire. As one executive stated, ‘The reasons for the difference are unclear, but management find comfort in the merging of mutual interests. Being acquired connotes being had!’ (Mace and Montgomery Jr. 1962, pp. 3–4)

For analytical purposes, it is common practice to distinguish M&A transactions with regard to the extent to which the activities of the acquired organizations are related to those of the acquirer (Cartwright and Cooper 2013). This kind of classification distinguishes four different categories of M&A transactions (Hovers 1973; Kitching 1967; Walter 1985).

- **Vertical M&A** is the combination of two companies from successive processes within the same industry with an actual or potential buyer-seller relationship (Cartwright and Cooper 2013). A company might, for example, choose to acquire a supplier (backward integration) or a firm that could distribute its products (forward integration) (Schweizer 2002).
- **Horizontal M&A** comprises the combination of two similar companies in the same industry and often occurs when the companies involved produce one or more of the same or closely related products or services in the same geographic area (Cartwright and Cooper 2013).
- **Conglomerate M&A** occurs when the acquired company is in a completely unrelated field of business activity (Cartwright and Cooper 2013). The rationale usually given for such M&A transactions is that the combination of the firms enables entry into an attractive business or industry and spreads the company’s risk (Schweizer 2002).

- **Concentric M&A** means a transaction where the acquired company is part of a new but related field into which the acquiring company wants to expand (Cartwright and Cooper 2013). This kind of M&A transaction is often referred to as product extension. It occurs when the acquiring and acquired companies are functionally related in a field but sell products or services that compete directly with one another.

Napier (1989) suggests a different categorization and outlines that M&A transactions can also be distinguished depending on the degree of integration that is needed to achieve the transaction objectives. Based on the integration approach, the following three types can be defined:

- In **extension mergers**, the acquiring company does not plan to change, other than perhaps marginally, the way in which the acquired company conducts its business (Napier 1989). This approach is also referred to as the “hands-off approach” (Schweizer 2002).
- In **collaborative mergers**, the success of the transaction depends upon the successful integration of operations (“synergy mergers”) or the exchange of know-how or other expertise (“exchange mergers”) (Napier 1989).
- In **redesign mergers**, the acquiring company plans to implement wide-scale changes, whereby the acquired company adopts the practices and procedures of the acquiring company (Napier 1989).

Post-merger Integration

The terms “post-merger integration” and “post-acquisition” refer primarily to the art of combining two or more companies after they came under common ownership – not just on paper but in reality. Integration occurs at several levels, e.g., by combining the IT, HR, or accounting systems of the previously independent companies or by creating a single legal entity. Other essential post-merger steps might be the integration of product lines, production systems, technologies, or other physical assets. Cultural integration

might be necessary as well. It is crucial to keep in mind that not all of these integration levels are always needed or planned. The degree of integration required and the fields of integration are determined by various contingencies (e.g., company culture, underlying strategy) and need to be planned carefully (Schweizer 2002).

During post-merger integration, it quite often comes to downsizing and restructuring: It is usually a stressful and demanding time for the companies and all people involved and needs to be executed skillfully and wholeheartedly. Researchers and practitioners have shown a keen interest in exploring the value-creating or destroying effects of M& transactions and found that a large number (around 50%) of M&As are not creating but destroying company value (Child et al. 2001).

Summary

M&A transactions are undeniable among the most intense and evident manifestations of strategy at the corporate level. With a single M&A transaction, the strategic course of the companies involved can be altered permanently (Schweizer 2002). With the help of such transactions, companies can gain fast access to technologies, products, distribution channels, personnel, or desirable cost and market positions. Therefore, one of the key challenges in managing M&A transactions is to make sure that these transactions support the firm’s overall strategy (Haspeslagh and Jemison 1991).

Definitions of Corporate Finance and Stylized Types of Financing

In economics, companies can be analyzed in various ways. Among other approaches, researchers try to model the “value created” by a company. From the perspective of the value chain concept, value creation is thought of as a series of activities performed by the firm. In contrast for corporate finance, companies are modeled as a system of cash flows (Berk et al. 2020; Brealy, Myers and Allen 2013). These cash flows are related to the value chain activities of a company (measured in quantities) and exactly flow in the opposite direction. Inflows and outflows are increasing or decreasing the company’s inventory of cash. For the operational activities of running its business, a company must maintain its financial equilibrium and avoid financial distress. Consequently, corporate finance can be defined activity-based: Financing covers all direct activities in each period to make the necessary amount of funds available. However, a second quantitative definition for financing is used to measure the development of the stock of cash in a company over time (the financing volume). This second perspective allows to distinguish between different types of financing (Nijs 2014).

Internal financing is defined as the negative or positive surplus between permanent inflows and permanent outflows which are necessary to operate the core business of a company (see Fig. 1). Accordingly, as a residual measure, internal financing might be a financial source or a financial

deficit. In contrast, external financing is a gross measure and is defined as positive inflows from different types of financial contracts closed on the financial market (see Fig. 1). Financial markets are basically defined by the exchange of funds between lenders and borrowers in a given institutional framework (Strumeyer and Swammy 2017). The resulting financial contracts are characterized by a temporary divergence between inflows and outflows in return. The financier will provide the promised amount of means of payment first. The company will pay the consideration (e.g., interest, redemption) in the future. Thereby, financiers are always exposed to negative developments during the contract period. This danger is referred to as financial risks (e.g., Reynolds and Hepinstall 2017). Hence, contracts on financial markets differ seriously from other exchange contracts resulting from spot transactions. In addition to the so-defined primary financial markets, unfulfilled financial contracts can be traded on secondary markets.

Financial contracts closed on perfectly competitive and complete financial markets are classified into stylized debt and equity contracts. This distinction results from the capital structure decision which must be made by financial managers (for

theories discussed, see Myers 2003). These perfect financial contracts can be compared to each other by their economic risks and chances. In literature four contract criteria are broadly accepted to model the risk profile of ideal financial contracts (e.g., Bernthal 2018): the claim on income, the claim on repayment, the rights of control, and the preference in insolvency (see Fig. 2).

Stylized debt contracts are characterized by fixed interest payments without any relation to the performance of the company (see Fig. 2). Also, the final redemption at the end of the term of the contract is fixed in advance. However, creditors are not having any rights of control. In case of financial distress, creditors are paid in preference to shareholders according to the insolvency regimes. Bank loans are close to this stylized debt contract.

Unlike stylized debt stylized equity contracts are characterized by a performance-related claim on income (see Fig. 2). Shareholders are not promised to receive a fixed amount of redemption after an initially determined term, but usually hand over their funds for the infinite lifetime of the company. In return, shareholders receive all rights of control (e.g., rights of information and rights of decision-making). In financial distress

Criteria	Stylized Debt	Stylized Equity
No Financial Distress		
Claim on Income	Fixed Interest Payments	Performance-related
Claim on Repayment	Fixed Amount and Term	Performance-related/ Infinite
Rights of Control	No Rights	All Rights
Financial Distress		
Preference in Insolvency	Yes	No (Residual Claim)
<i>Example</i>	<i>Bank Loan</i>	<i>Common Shares</i>

ideal shareholders will not be paid in preference. Common shares are close to this stylized equity contract. However, the detailed legal position of a shareholder depends on the legal form of the company and the special regulations in the statutes of a company.

Mezzanine Financial Contracts

There is a broad spectrum of financial contracts between the stylized equity and debt contract. The stipulations of these contracts are referring to criteria from debt *and* equity contracts. As showing characteristics of both types of contracts, they are defined as mezzanine or hybrid instruments (Nijs 2014). The process of creating mezzanine financial contracts is a moving target and is a response to imperfections on financial markets and their incompleteness. Hence, in research they are labeled as financial product innovations (Nejad 2021; OECD 2018; Nejad 2016; Tufano 2003). In line with *Schumpeter's* concept of competition and innovation, financial innovation can be defined as a permanent process of experimentation leading to new institutions, instruments, techniques, and markets (Awrey 2011). Basically, changes in the financial environment will stimulate the search for new financial products. These changes can be classified into four types: response to changes in the demand conditions, response to changes in supply conditions, avoidance of financial market regulation, and

response to advances in technology (Mishkin and Eakins 2018). Consequently, the creation of new mezzanine financial contracts is in constant flux (OECD 2015). However, a basic taxonomy of mezzanine finance can refer to the life-cycle model of companies (see Fig. 3) and the degree of standardization of the financial contract. While private mezzanine financial contracts can be negotiated individually, public mezzanine financial contracts are characterized by the full standardization of the elements of the contract by the issuer. Hence, public mezzanine financial contracts are usually exchange traded.

The financing landscape for start-ups (see early stage, Fig. 3) is characterized by a lack of information to investors for two reasons. First, private companies not listed on stock markets are not legally obliged to disclose financial accounting information. Second, providing information on business activities and financials is costly for a small or medium-sized company. Due to the corresponding informational risks, companies in the early stage of the company's life cycle have limited access to the financial market. Accordingly, mezzanine financial contracts emerged and help to bridge the gap between entrepreneurs and financiers. In the early stage private mezzanine financial contracts are in the limelight of financiers. Currently, mezzanine financial contracts are quite popular on crowdfunding platforms (OECD 2015). Some examples of private mezzanine equity contracts are given below:

Mezzanine Finance,
Fig. 3 Life-cycle model of companies (source: own figure)

- *Silent participation:* Although some basic regulation might be found in national company law, silent participation is an individually contracted financial instrument (e.g., Demaria 2020). Financiers typically get asymmetric claims on income. Silent partners participate in positive company's income but do not participate in company's losses. Accordingly, this element is close to a stylized debt contract. Typically, rights of control are not limited and remain close to a stylized equity contract. In case of bankruptcy, silent participation has no preference. Silent participation is an internal agreement and is not communicated to the public.
- *Profit participating rights:* Since the holder of this type of financial contracts is entitled to participate in performance-related claims on income and repayment, they meet the criteria of a stylized equity contract. However, they do not have any rights of control and are not consulted on business decisions. Typically, these rights have subordinated preferences in insolvency. In a nutshell, owners of profit participating rights simply hold a right to a specific monetary claim (Nijs 2014).

Besides, start-up companies might not qualify for stylized debt contracts (represented by a bank loan) since the business model does not fit the criteria of the applied scoring system or past projects were not successful. Hence, in addition to private mezzanine equity, private debt mezzanine financial contracts are important in the early stage as well and some examples are given below:

- *Subordinated loans:* Subordination of debt contracts can be fixed contractually to three of the criteria introduced above: the claims on income and repayment and the preference in insolvency. Accordingly, a broad variety of subordinated loans evolved on financial markets (Demaria 2020).
- *Profit participating loan:* Another possible mechanism to compensate creditors for the high financial risks in the early stage is some sort of profit participation. Accordingly, the claim on income is now performance-related or provides conversion rights and fits the criterion of a stylized equity contract. However, rights of control usually are not given to the financiers (Nijs 2014).

In the growth and maturity stage of a corporation (see Fig. 3), the mitigation of financial risks by mezzanine financial contracts is at the center of interest as well. In contrast to the early-stage, grown-up companies have access to regulated financial markets (e.g., the stock exchange and the bond market). Therefore, public mezzanine financial instruments are often used in this stage. Two examples are given below:

- *Preferred shares:* Unlike common shares, this class of shares includes specific rights (Liberadzki and Liberadzki 2019; Nijs 2014). These rights are negotiated between market participants depending on their perception of the risk-chance profile of the company. For example, a preferred claim on income or a preferred redemption with a guaranteed minimal multiple of the contribution is negotiated. Besides, some preferred shares are designed with a limitation of the rights of control.
- *Convertible bonds:* Convertibles are debt contracts that include the option to be converted into common shares of the issuing company (Brigham 1966). The basic features of convertibles are the pre-determined conversion market price and the conversion time or period. However, many special features may be negotiated in addition (Dutordoira et al. 2014; De Spiegeleer et al. 2014). Before the conversion, the convertible bond has the rights of a stylized debt contract.

Finally, mezzanine financial contracts occur in the decline stage of a company (see Fig. 3). Different types of buyouts (e.g., management buyout or leveraged buyout) are used to take a company with publicly traded shares private, and mezzanine debt contracts are used to finance these kinds of transactions (Anson et al. 2011). Another function of mezzanine contracts in this stage is to support company in financial distress (Anson

et al. 2011) and provide plans for the restructuring of the business (e.g., debt-equity swaps).

In conclusion, the preference of companies for mezzanine financing is attributed to financial market imperfections and incompleteness (Myers 2003). For the specific decision companies will rely on a set of criteria (Nijs 2014). Two of them are explained below:

- (1) Classification of the mezzanine instrument in financial accounting: Basically, this criterion refers to the mitigation of informational risks. Financiers want to receive reliable information on the development of future cash flows and perform a financial statements analysis to predict the ability to pay back loans. Among other ratios, the leverage of a company is in the limelight of the analysis. Hence, the recognition of a mezzanine financial instrument as equity on the balance sheet is important and the preference in insolvency must be considered.
- (2) Financing costs: Since mezzanine financial instruments are usually contracted when the traditional financial market for debt contracts is not accessible for a company (Nijs 2014), they are more expensive than a traditional bank loan. Financiers will ask for a premium due to the mitigation of financial risks, for example, subordination in bankruptcy. Contrarily, the financing cost is typically lower than the cost of equity because some equity owner rights (e.g., decision-making rights) are not given to the mezzanine financier. However, due to the broad range for the design of the compensation, mezzanine financials are very flexible and can be tailored to special financial needs of the company.

Providers of mezzanine financial contracts can be categorized into non-sponsored and sponsored financiers (Nijs 2014). Whereas non-sponsored financiers are typically financial intermediaries (banks, funds, etc.), the sponsored financiers are often private equity firms (Demaria 2020). Since mezzanine financing is used for sustainable development initiatives, development banks are a major player on the market as well, and alternative financial instruments are the

focus of political initiatives (OECD 2015, 2018). One important field of application is the transformation of the financial system to sustainable finance (Juan et al. 2019). According to their features, “Green Bonds” are an example of mezzanine financial contracts.

Example for Mezzanine Financial Contracts: Green Bonds

The growing interest in sustainable finance innovations by investors and advantages from the issuers’ perspective, for example, reputation in the maturity stage, led to the emergence of the “Green Bond” markets. Initially, this term was used exclusively for bonds issued to finance environmentally friendly activities (Bagnoli and Watts 2020). The first corporate green bond was issued by Toyota in 2013 to finance cars with hybrid engines. Although to date a legal definition of green bonds is missing, many market participants agree on extending the definition of green bonds to all bonds whose funds are used to finance socially responsible activities (economic-social-governance factors). However, in some context the term of GSS bonds (green, social, sustainability) is used (e.g., Climate Bond Initiative (CBI) 2020).

Since the funds generated by green bonds are earmarked to finance sustainable activities, some features of these bonds differ from those of stylized bonds and support the corporate governance function. First, the claim on income and repayment can be related to the success of the sustainable project financed exceptionally. Second, rights of control are given to investors typically to monitor the success of the projects ex-ante and ex-interim (Park 2018). These rights are a special type of non-financial covenants which are developed to mitigate the risk of insolvency (Berk et al. 2020). Finally, the green bonds are ranked *pari passu* to other bond investors in bankruptcy. Due to this special contract design, the financing costs of some green bonds sometimes are below the costs of traditional bond. This negative premium is called the “greenium” (Agliardi and Agliardi 2021).

Green, social, and sustainability bond issuance doubled in 2020

Mezzanine Finance, Fig. 4 The growing market for GSS bonds (source: CBI 2020)

The emergence of green bonds seems to be a great success story: At the end of 2020, the sustainable debt market had reached USD1.7tn, and almost 10,000 instruments had been issued under GSS labels since 2006 (see Fig. 4). However, investors in green bonds face the risk of greenwashing, since the issuer's promise to fund socially responsible activities is open to fraud (Bagnoli and Watts 2020).

To enhance the role of hybrid financial instruments in the transformation of the financial system, the European Union is in a leading role: In 2018 the action plan on sustainable finance was adopted by the European Commission. Based on this plan, an EU Taxonomy to determine whether an economic activity is environmentally sustainable and meets minimum social safeguards is developed, and an EU Green Bond Standard is designed (Zetzsche and Anker-Sørensen 2021; Schütze and Stede 2021).

MDGs; Millennium Development Goals

Definition

The Millennium Development Goals (MDGs) were a United Nations (UN) initiative, describing eight goals for international development with the overall objective to improve global living standards.¹ The MDGs were defined in the year 2000 by a large intergovernmental conference at the United Nations in New York (the “Millennium Summit”), in which representatives from 189 governments committed themselves to achieve these goals within 15 years. The eight goals are related to poverty reduction, education, gender equality, the reduction of child mortality, maternal health, the combat of diseases like HIV/AIDS or malaria, environmental sustainability, and a global partnership for development. Most goals included the

¹ A comprehensive overview can be found in Briggs, 2018; Gauri, 2012; Sultana, 2020.

target year of 2015 – mostly with reference to the status quo in 1990. The eight MDGs represented a widely “shared vision on development” (Herfkens, [n.d.](#)). Within the framework of the MDGs, it was acknowledged that developing countries would not be able to reach these goals without support from the developed world. The MDGs were partly achieved by 2015 and succeeded by a set of 17 Sustainable Development Goals (SDGs), established in the Post-2015 Development Agenda, and intended to be accomplished by 2030.²

The Pathway to the Millennium Development Goals (MDGs)

As early as the 1990s, a number of the topics that were finally summarized in the MDGs were discussed in several international conferences, for example, during the World Summit on Social Development in Copenhagen in 1995. In May 1996, the Development Assistance Committee (DAC) of the Organization for Economic Cooperation and Development (OECD) published a report entitled “Shaping the 21st Century,” which proposed a global development partnership to achieve six development goals in the areas of “economic well-being,” “social development,” and “environmental sustainability and regeneration” – with a clear time frame until 2015. The report also reemphasized the target that developed countries should spend 0.7% of their Gross National Income (GNI) on Official Development Assistance (ODA) – a goal established by the United Nations in 1970 as an appropriate level for foreign aid. Building on these developments, the UN General Assembly resolved in 1998 to hold a Millennium Summit, prepared by the UN General Secretariat. In this context, the UN Secretary-General, Kofi Annan, published a report in early 2000 (“We the Peoples: The Role of the United Nations in the 21st

Century”), in which he recommended that the planned Millennium Summit should adopt specific goals on the issues discussed during the Copenhagen Summit in 1995.

The Millennium Declaration

The “Millennium Summit,” held from September 6 to September 8, 2000, in New York, brought together representatives from 189 countries, among them 100 heads of state, 47 heads of government, and approximately 8,000 further delegates – by then the largest meeting of world leaders. It aimed at discussing and defining a vision for the role of the UN in the twenty-first century as well as defining goals to improve living standards, particularly in developing countries. The Millennium Summit was cochaired by the Finnish president Tarja Halonen and the president of Namibia, Sam Nujoma. Finland and Namibia had chaired the 54th and 55th UN General Assembly sessions. The summit was opened by UN Secretary-General, Kofi Annan, followed by speeches of world leaders – among others Bill Clinton, Vladimir Putin, Jiang Zemin, Thabo Mbeki, Zine el Abidine Ben Ali, Yoshiro Mori, and Robert Mugabe. The results of the discussions were finally adopted as the “United Nations Millennium Declaration” by the 55th session of the UN General Assembly on September 18, 2000, in New York (UN, [2000](#)). In this declaration, the signatory parties

- addressed the core values and principles of the UN and its member states, particularly the values of freedom, equality, solidarity, tolerance, respect for nature, and shared responsibility,
- expressed the willingness to support the UN in its attempt to work for peace and security,
- promised to eradicate poverty, to work for development, and to fight the destruction of the natural resources on earth,
- resolved to promote democracy and human rights and to protect vulnerable groups,
- supported the consolidation of democracy specifically in Africa, and

²For an interdisciplinary literature review on the limitations of the MDGs, see: Fehling et al., [2013](#).

- claimed to strengthen the UN as an organization.

Although the eight MDGs were not explicitly mentioned in the Millennium Declaration, it did contain their key substance already. In a process of specification and concretization, the eight MDGs were finally elaborated from the text of the Millennium Declaration. The guiding idea was to define an “overarching development framework for the world” (UN, 2015) for the period until 2015 (for most of the targets). The Millennium Development Goals were explicitly mentioned for the first time in September 2001 in a “Road Map towards the Implementation of the United Nations Millennium Declaration,” which was presented to the General Assembly by UN Secretary-General Kofi Annan. However, some aspects mentioned in the declaration did not find their way into the MDGs, mainly those statements that circled around questions of governance, transparency, and human rights. Overall, the process of defining and elaborating the MDGs can be described as rather ad hoc and not very systematic.

The Millennium Development Goals (MDGs)

The following MDGs were made concrete with the help of 21 targets:

Goal 1: Eradicate extreme poverty and hunger

- 1A: Halve the proportion of people living on less than 1.25 US\$ a day.
- 1B: Achieve decent employment for women, men, and young people.
- 1C: Halve the proportion of people who suffer from hunger.

Goal 2: Achieve universal primary education

- 2A: All children can complete a full course of primary education.

Goal 3: Promote gender equality and empower women

- 3A: Eliminate gender disparity in primary and secondary education.

Goal 4: Reduce child mortality

- 4A: Reduce by two-thirds, the under-five mortality rate.

Goal 5: Improve maternal health

- 5A: Reduce by three-quarters, the maternal mortality rate.
- 5B: Achieve universal access to reproductive health.

Goal 6: Combat HIV/AIDS, malaria, and other diseases

- 6A: Have begun to reverse the spread of HIV/AIDS.
- 6B: Achieve universal access to treatment for HIV/AIDS for all who need it (by 2010).
- 6C: Have begun to reverse the incidence of malaria and other major diseases.

Goal 7: Ensure environmental sustainability

- 7A: Integrate the principles of sustainable development into country policies and programs; reverse loss of environmental resources.
- 7B: Reduce biodiversity loss significantly (by 2010).
- 7C: Halve the proportion of the population without sustainable access to safe drinking water and basic sanitation.
- 7D: Achieve significant improvement in the lives of at least 100 million slum-dwellers (by 2020).

Goal 8: Global partnership for development

- 8A: Develop further an open, rule-based, predictable, nondiscriminatory trading and financial system.
- 8B: Address the special needs of the Least Developed Countries (LDCs).

- 8C: Address the special needs of landlocked developing countries and small island developing states.
- 8D: Deal with the debt problem of development countries.
- 8E: Provide access to affordable, essential drugs in development countries.
- 8F: Make available the benefits of new technologies, especially information and communications.

Most targets were backed by very concrete and measurable indicators. For instance, target 8D (“Deal with the debt problems of development countries”) would be measured by net ODA, total and to the Least Developed Countries (LDCs), as a percentage of OECD/DAC donor’s GNI, by ODA received in landlocked countries as proportion of their GNIs, by average tariffs imposed by developed countries on agricultural products and textiles from developing countries, or by the debt service as a percentage of exports of goods and services. It is interesting to note that some of the targets include commitments not only for the developing world, but also for developed countries. This is particularly true for goal 8 that primarily addressed developed countries and called for a reform of trade policies, ODA, subsidies in agricultural policies, and debt relief.

Implementation and the Path to “Sustainable Development Goals” (SDGs)

It soon became clear that in order to achieve the MDG targets, it was necessary to link activities on the global level with activities on the regional, the national, and even the local level. On all of these different levels, activities of not only governments were needed, but also of non-governmental organizations (NGOs), transnational corporations (TNCs), and even by individuals. In order to bring together these different types of stakeholders and to mobilize support for the MDGs, the “Millennium Campaign” was initiated by Secretary-General Kofi Annan

in 2002.³ However, the creation and implementation of action plans at the national level remained the decisive and critical success factor for the implementation of the MDGs. The United Nations Development Group (UNDG) was primarily responsible for the global and country-specific monitoring of progress in achieving the goals. On the basis of the World Bank’s Development Indicator, the UN Department for Economic and Social Affairs (DESA) Statistics and Population Divisions, and the UN Development Programme’s (UNDP) annual Human Development Reports, evaluations of the achievement of the MDGs were continuously published in several global and regional reports. Additional initiatives, like the privately funded “MDG Monitor,”⁴ also tracked progress on the national and global level. Some of the goals were also developed further – such as in the Johannesburg Plan of Action, which provided for more detailed target dimensions and timetables, for example, in wastewater disposal, the sustainable use of the oceans, or the regeneration of fish stocks.

A comprehensive intermediate evaluation of the progress was carried out at a large UN conference in September 2010 (“Review Summit 2010”). The MDG Report 2010, prepared by UN Secretary-General Ban Ki Moon in preparation of the summit, stated that “many countries are moving forward, including some of the poorest, demonstrating that setting bold, collective goals in the fight against poverty yields results. For every life that has benefited from the establishment of a quantitative, time-bound framework of accountability, the MDGs have made a real difference. But unmet commitments, inadequate resources, lack of focus and accountability, and insufficient dedication to sustainable development have created shortfalls in many areas” (UN, 2010). The review summit therefore proposed to accelerate the process to meet the targets by 2015.

The final MDG report from 2015 was then put together by a group of experts from various UN agencies and International Organizations under

³Cf. Herfkens [n.d.](#)

⁴Cf. www.mdgmonitor.org

the leadership of the UN Department of Economic and Social Affairs (UN DESA). The progress chart from 2015 shows good progress or “target met” status for most MDGs in most world regions. However, it also identifies poor progress or even deterioration in some cases, particularly in Oceania, Western Asia, or Northern Africa. The report mentions the following achievements of the MDG process (UN, 2015, 4–7):

Goal 1: Eradicate extreme poverty and hunger

- Extreme poverty rate⁵ in developing countries dropped from 47% (1990) to 14% (2015).
- The absolute number of people living in extreme poverty has declined from 1926 million (1990) to 836 million (2015).

Goal 2: Achieve universal primary education

- The number of out-of-school children of primary school age has fallen from 100 million (2000) to 57 million (2015).
- Literacy rate among 15–24 year-olds has increased from 83% (1990) to 91% (2015).

Goal 3: Promote gender equality and empower women

- The developing regions have achieved the target to eliminate gender disparity in primary, secondary, and tertiary education.
- The average proportion of women in parliaments has nearly doubled between 1995 and 2015 (however, still only 20% MPs are female).

Goal 4: Reduce child mortality

- Child (under five) mortality rate has dropped from 90 deaths per 1000 live births (1990) to 43 (2015). Also, the absolute number of deaths of children under five has decreased despite population growth.

Goal 5: Improve maternal health

- Global maternal mortality ratio per 100,000 live births has declined from 380 (1990) to 210 (2015).
- Global births attended by skilled personnel have increased from 59% (1990) to 71% (2014).

Goal 6: Combat HIV/AIDS, malaria, and other diseases

- New HIV infections fell from an estimated 3.5 million (2000) to 2.1 million (2013).

Goal 7: Ensure environmental sustainability

- Access to piped drinking water has increased from 2.3 billion (1990) to 4.2 billion (2015).
- Ozone-depleting substances have been eliminated between 1990 and 2015.

Goal 8: Global partnership for development

- ODA from developed countries has increased by 66% from 81 billion US\$ to 135 billion US\$.
- The proportion of external debt service to export revenue in developing countries fell from 12% (2000) to 3% (2013).

Already in 2012 – still during the MDG-period – the UN Secretary-General started to work on a “Post-2015 Development Agenda,” a process that involved many UN agencies, international organizations, civil society organizations, and research institutions. The objective of the Post-2015 Agenda was to build on the success of the MDG process, but it also takes into account its weaknesses. It establishes a broader framework of “Sustainable Development Goals” (SDGs) for the time when the MDGs expired in 2015.⁶ The Post-2015 Agenda also called for a greater participation of people living in poverty, civil society

⁵Defined by less than 1.25\$ per day.

⁶The transition from “MDGs” to “SDGs” – partially also in a comparative approach – is covered by Chivanga & Monyai, 2021; de Jong & Vijge, 2021; Rosenbaum, 2015; Sachs, 2012; Solberg, 2015; Vandemoortele, 2017 and Vandemoortele, 2018.

actors, and developing countries in the process of defining the next generation of goals (see Manning et al. 2013).

Critical Assessment

The 2015 UN MDG report speaks of “profound achievements” and concludes with a positive overall assessment: “The world community has reason to celebrate. Thanks to concerted global, regional, national and local efforts, the MDGs have saved the lives of millions” (UN 2015). Most scientific analyses⁷ come to a more mixed picture. Overall, significant progress was made between 1990 and 2015 in the field of human development; however, the impact of the MDGs on this progress is difficult to assess. Although a causal link between the MDGs and progress in human development cannot be made – due to the lack of a counterfactual scenario – some researchers have stressed the importance of the MDG-process in increasing awareness and combining forces of the international community.⁸ Yet, success of the MDGs stems to a large degree from strong economic development in China, while in other world regions there has been a deterioration in some of the targets. Even the UN MDG Report 2015 itself admits that only one target was actually met in Sub-Saharan Africa (namely, the reverse of the spread of HIV/AIDS). And “whilst the world has made significant progress during the MDG-era, none of the global targets were met” (Vandemoortele, 2018, 84). Vandemoortele (2018) – using a traffic-light scheme – still assigns “green” to areas like poverty, hunger, child mortality, maternal health, drinking water, and infectious diseases; “orange” to areas like basic education and gender equality;

and “red” to goal 8 on the global partnership for development. He bases this assessment specifically on the observed failure of developed countries to increase their foreign aid to the agreed target of 0.7% of GNI. Furthermore, he assesses the efforts in the MDG process in the field of environmental policy as a failure. In summary, Vandemoortele (2018, 84) judges: “Progress for people, regress for the planet” – an assessment that also justifies the increased efforts in the post-2015 phase to pay more attention to sustainability as a critical aspect of human development. Another aspect that has to be taken into account is that for certain groups, particularly stigmatized or “devalued identities” (Kabeer, 2006), success levels have been lower than for other people.⁹

Despite all these difficulties and problems, the MDG process remains a good – and at least partly successful – example of setting a normative frame of reference that has had a guiding effect on many governmental and nongovernmental actors. The discussion on the MDGs and their implementation inspired the debate on a broader concept of poverty, as discussed by Amartya Sen and others. A central shortcoming of the MDGs has turned out to be the rather subordinate role of the thematic field of climate change, which was formulated in MDG 7 but remained underexposed in its importance also for the interaction between poverty and environmental issues.

Milton Friedman

Sascha Genders
IHK Würzburg-Schweinfurt, Würzburg,
Germany

Definition

Milton Friedman was an US-American economist, born July 31, 1912, in New York, and died November 16, 2006, in San Francisco. He is considered one of the most influential economists of the twentieth century. In 1976, Friedman received the Alfred Nobel Memorial Prize in Economic Sciences. He was honored for his research into

consumption analysis and his contributions to monetary history and monetary theory and to the complexity of stabilization policy. Friedman is considered a pioneer of modern monetarism. He also made important contributions to discussions on topics such as corporate responsibility (bpb 2022; Woll 2018).

Basic Biographical Information

Milton Friedman was born on July 31, 1912, in New York. He died on November 16, 2006, in San Francisco. He began his academic teaching career in 1946 at the University of Chicago and completed it there in 1977. This was followed by positions at the Federal Reserve Bank of San Francisco and a collaboration with the Hoover Institute at Stanford University. Friedman is one of the most influential economists of the twentieth century (bpb 2022; Woll 2018).

Friedman was one of the scholar and initiators of the so-called Chicago School of Economics, a group of economists from the University of Chicago and a school of thought of the same name, which, among other things, vehemently advocated the dogma of free markets. The free market was seen as the best way of allocating resources efficiently (Ebeling 2006).

His life's work includes an enormous number of different topics from monetary policy, business ethics, and trade policy to questions of educational policy. So, Friedman's economic legacy includes a variety of books, academic papers, publications, and television series. Perhaps, his best-known works include "The Methodology of Positive Economics" (Friedman 1953), "The Quantity of Theory of Money: A Restatement" (Friedman 1956), "A Monetary History of the United States, 1867–1960" (Friedman 1963), and "The Social Responsibility of Business Is To Increase Its Profits" (Friedman 1970).

Major Contributions

Milton Friedman dealt, among other things, with the importance of monetary policy and the status

of the state and the market, as well as with questions of corporate responsibility and their impact. Here, we focus on so-called monetarism and the discussion on the role of corporations in the economy. On the one hand, this is about the importance of the state and monetary policy in shaping economic growth (see a. Monetarism and the Role of the State). On the other hand, the objective of a company, the generation of profits, comes into focus (see b. Responsibility and Corporate Profits).

Monetarism and the Role of the State

Milton Friedman's legacy is closely linked to the concept of so-called monetarism. This monetarism is closely linked to the idea of a so-called supply-oriented macroeconomics and corresponding economic policy, in which the task of the state is to define general economic conditions instead of directly intervening in market mechanisms (bpb 2022; Conway 2011; Leschke 2012; Woltmann 2018).

Significantly influenced by the work of Friedman (1956), monetarism focuses (without going into detail) on a monetary policy that is closely related to the available money supply (put simply: the amount of money in an economy) and their relationship to the existing price level and prevailing price increases (inflation). At the same time, Friedman sees the money supply as the most important lever of economic policy and for controlling economic growth: According to Friedman, an ideal level of economic growth can best be achieved with a certain growth rate of the money supply. If monetary policy succeeds in ensuring constant money supply growth and aligning this with the growth in economic power, economic momentum will stabilize in a positive sense. Inflation (monetary instability), on the other hand, exists when there is too much money "in circulation" in an economy. More money in the economic cycle promotes willingness to consume and invest, which in turn leads to rising prices. On the other hand, if there is not enough money in circulation, the willingness to consume and invest falls and prices fall (deflation). In order to achieve price stability (monetary stability), it is also the task of monetary policy to

get these inflationary/deflationary tendencies under control by controlling the money supply (bpb 2022; Conway 2011; Leschke 2012; Woltmann 2018).

Except for monetary policy, Friedman relies on “market forces.” He rejects state measures, for example to combat unemployment or other concepts of economic policy. This applies regardless of whether the economy is in a phase of economic upturn or downturn: Measures to promote investment in times of crisis or raising taxes in boom phases amplify economic fluctuations and have a destabilizing effect. Friedman is clearly in favor of strengthening market forces. Ideally, this would be flanked by the monetary policy of the central banks, which Friedman believes is much more effective than state tax and fiscal policy. He relies on privatization and deregulation as well as a policy of *laissez-faire* as the core of his considerations. State economic policy activities should be largely reduced. This is the only way to achieve a steady upward trend in an economy (bpb 2022; Conway 2011; Leschke 2012; Woltmann 2018).

In conclusion, the logic of monetarism and thus Friedman’s perspective leads to a rejection of an anticyclical economic policy in the sense of Keynes. This in turn means that an anticyclical economic policy is unsuitable. The US-American John Maynard Keynes (1883 to 1946), perhaps the best-known economist of the twentieth century before Friedman, who advocated the Keynesian approach, based his economic policy on a demand orientation instead of the supply-oriented perspective. Accordingly, aggregated demand determines the performance of an economy. Ergo, in addition to monetary policy, is also the task of the state to influence the economic situation through fiscal policy measures. In times of crisis, for example, tax cuts and government investment and public debt could improve the situation. Friedman, on the other hand, argues against the possibility that the state can use revenue and expenditure policies to stabilize an economic cycle in the long term. His policy of *laissez-faire* is contrary to this view of Keynes (bpb 2022; Conway 2011; Leschke 2012; Woltmann 2018).

Responsibility and Corporate Profits

An article by Milton Friedman published in the New York Times in 1970 (NY Times, 1970) deserves special attention regarding the topic of corporate social responsibility and the task of companies. The title “The Social Responsibility of Business Is to Increase its Profit” makes it clear how Friedman defines the (social) responsibility of entrepreneurs: in increasing the company’s profits.

According to Friedman, the task of the manager of a company is exclusively to increase the profit of the company. Friedman argues that the focus on profits must always take place within the framework of existing regulations, laws, morals, and ethics. The shareholder value concept developed from this approach (Heldt 2018; Leschke 2012). In relation to the purpose of a company, this strategic goal is about increasing the value of the shareholders – for example, the shareholders of a listed stock corporation. In order to take up the goal of profit maximization, there are many approaches that argue that it is ultimately crucial how profits are generated and that their use is also important for assessing how companies are perceived; in other words, the mere intention to generate profits is not negative (Genders 2021). The critics of this point of view argue that it is precisely this point of view and behavior of companies (maximize their own profit) that contributes to promoting social inequalities, poverty and hunger, climate damage and environmental pollution, or the exploitation of people (Buchter 2020).

The shareholder value approach is opposed to the so-called stakeholder value approach, according to which the company management not only considers the interests of the shareholders, but all stakeholder groups. A company and in particular the management aims to consider the various stakeholder groups – owner, employee, customer, supplier, or state – in a cooperative sense and to place their interests at the center of the corporate strategy (Breuer 2018; Leschke 2012).

Honors and Miscellaneous

Friedman received a variety of awards throughout his life. Particularly noteworthy is the Alfred

Nobel Memorial Prize in Economic Sciences, which he received in 1976 for his work on monetary history and monetary theory and for his studies on consumption analysis and on the complex of stabilization policy (bpb 2022; Woll 2018).

Friedman's work had a significant influence on the politics of his time: He was an advisor to US Presidents Richard Nixon (President from 1969 to 1974) and Ronald Reagan (President from 1981 to 1989) and shaped the phase of the so-called "Reaganomics" for the latter (Reagan-Economics jargon), a period of US economic policy characterized by diminishing government influence and spending cuts, deregulation, or reductions in tax rates to encourage economic dynamism. He also helped shape the former Prime Minister of the United Kingdom Margaret Thatcher (Prime Minister from 1979 to 1990) and her "Thatcherism," which was the same in terms of content (bpb 2022; Woll 2018).

With a view to the later years of his life, Friedman also distinguished himself as a source of economic policy ideas and impulses for a broader audience. His work "Free to Choose" (Friedman and Friedman 1980), published in 1980, was one of the first nonfiction books that took up economic topics far away from a specialist audience. The book was accompanied by its own television documentary.

Summary

Friedman is one of the most influential economists of recent times and has shaped many issues. Two important areas of activity were the monetarism and the debate about the importance of monetary policy and the role of the state in controlling economic growth. Friedman himself had great faith in market forces. It was the task of the state to define general economic framework conditions, but not to intervene in the market itself. He rejected an anticyclical economic policy. In addition to monetarism, Friedman has also made an important contribution to the debate on the role of corporations in society. In his view, it is the task of companies to generate profits.

Mindful Consumption

► Consumer Social Responsibility (CnSR)

Mindfulness

Nirmala Lee
Guildhall School of Business and Law, London
Metropolitan University, London, UK

Synonyms

Being present in the present; Heedfulness; Introspective awareness

Definitions and Description

Mindfulness is etymologically derived from Pali *सति* (sati) and Sanskrit *स्मृति* (smṛti) and refers to awareness/attention/heedfulness, a spiritual or psychological quality that forms an essential part of Buddhist practice. Correct/right mindfulness (Pali: *sammā-sati*, Sanskrit *samyak-smṛti*) is the seventh element of the Eightfold Path propounded as “Noble” by the Buddha. The Buddhist concept has acquired wide currency in recent times as a psychological process of bringing one’s attention to experiences in the present moment through mental strategies such as meditation: This could involve focusing on one’s current physical and psychological state. For example, the focus could be on the depth, timing, and type of one’s breath and awareness of surrounding noises and smells. The concept has been applied in a number of areas including healthcare, workplace practices, and sustainability. In the Satipatthana Sutta, the Discourse on the

Foundations of Mindfulness, the Discourse on the Foundations of Mindfulness, attributed to Buddha (circa sixth to fourth century BC) and translated by Thera (1998), mindfulness is to be meticulously and carefully aware and attentive in relation to the following four forms of mental culture or meditation: (1) the activities of the body (kaya), (2) sensations or feelings (vedana), (3) the thoughts going on in the mind (citta), and (4) reflections, imagination, and related matters (dhamma). Phronesis is essentially a Greek concept from the west that has a parallel of the Buddhist concept of mindfulness from the east (McEvilley 2002).

Grossman (2019:102) points out that mindfulness is “predicated upon long-term cultivation of introspective awareness of lived experience”; he is of the view that the definition of mindfulness is multifaceted and it requires large amounts of individual experiential learning to acquire expertise. While many scholars examining the concept of mindfulness may not have achieved the high level of expertise required by Grossman as set out in his argument, mindfulness is now considered to contribute to effective decision-making on all matters that affect humanity including sustainability-related matters.

Mindfulness and Policy-Making

Mindfulness has implications for political processes and policy-making (Luberto et al. 2018), and this in turn has implications for effective political and policy interventions in regard to sustainability issues which require be addressed by the evaluation of metrics and data as well as by human qualities and values. Bristow (2019) outlines the growing influence of mindfulness on politics and policy-making.

In April 2014, the UK politicians formed an All-Party Parliamentary Group on Mindfulness (MAPPG); this group was a non-artisan organization drawn from members of the House of Commons and the House of Lords formed with the purpose of developing ideas and proposal that could translate into policy. The group that conducted a one-year investigation into the existing practice and future potential for mindfulness in

public life involved the use of meditation in political thinking (Cook 2016:141). Conclusions and recommendations further action were published in what was the very first policy review of mindfulness titled “Mindful Nation UK” (2015).

Mindfulness and Sustainability

Attempts have been made to demonstrate a possible relation between mindfulness, sustainable consumption patterns, unsustainable consumption patterns, and life satisfaction. Dhandra (2019) observes that mindfulness is positively correlated with green credentials and frugality, while being negatively correlated with materialism. He argues that individuals with greater mindfulness are less likely to engage in unsustainable consumption patterns and more likely to be associated with satisfaction with life. There is scope for utilizing mindfulness in order to successfully implement sustainable strategies and enhance satisfaction with life. Mindfulness plays a significant role in motivating individuals for a shift in behavior towards sustainability (Ericson et al. 2014; Fischer et al. 2017; Dhandra 2019).

Geiger et al. (2019) review twelve empirically researched papers during the period commencing 2005 and concluding 2013, on five diverse pathways in which mindfulness has been considered as impacting on sustainable behaviors; the potential areas for promoting sustainable consumption behaviors through mindfulness are identified as under:

1. *Disturbance in relation to routines*
2. *Consistency in respect of attitude and behavior*
3. *Altruism, cooperation, and sharing*
4. *Values and Meaning in life*
5. *Health and wellbeing*

The concept of disruption of routines referred to the process whereby mindful awareness could interrupt the automated thought processing, or “autopilot” being; the disruption could enable people to become aware of unconscious consumption that could be unsustainable. Secondly, mindfulness could lead to the translation of intentions

and attitudes into more sustainable behaviors. Thirdly, mindfulness practice could increase compassion and strengthen socially responsible consumption behavior such as consumption of fairly produced garments. Fourthly, mindfulness could be related to a positive construction of meaning and values in life, as opposed to materialistic or hedonist values. Finally, evidence of the positive impact of mindfulness on different health dimensions, such as sleep, feeling of well-being, and health indicators, was noted.

Recent Research on the Impact of Mindfulness on Gut Microbiome

Recent research has revealed strong linkages between mindfulness and good health. Good gut bacteria such as *Prevotella*, reported to be low in autistic as well as depressed children and adults, were seen to have multiplied several fold in Tibetan monks who practiced mindfulness leading to deep meditation. It has been suggested that the ways of practicing mindfulness include the repetition of the words *Who cares. So what. No big deal.* Kirtan Kriya that involves the repetition of the words *Saa (Beginning) Taa (Existence) Naa (Transformation) Maa (Rebirth)* has also been referred to as promoting mindfulness. Good results included mental calm as well as physical benefits of improved gut health. See, for example, Kamiya (2022) and Burgess (2023).

Concluding Comments

The term mindfulness flags up the need for thought in action in all areas, and this includes the areas relating to sustainability. It is crucial that what is done is informed by mindfulness. Mindfulness is an intellectual state that must be acquired through practice of awareness. Like the concept of *phronesis* envisaged by Socrates, Plato, and Aristotle, mindfulness as envisaged by Buddha enables a person to identify “the right way to do the right thing in a particular circumstance, with a particular person, at a particular time” (Schwartz and Sharpe 2010:5–6).

Sustainability is concerned with initiatives that include preventing the world from being environmentally degraded and depleted and the reduction of all kinds of pollution. The aim is to preserve the long-term health of eco systems. Mindfulness is crucial in a world filled with tradeoffs and riddled with uncertainties; what Eisner (2002:375) observes in relation to phronesis applies equally to mindfulness: “it deals with contingencies, is iterative and shifts aims in process when necessary. . . Its aim is to arrive at good but imperfect decisions with respect to particular circumstances.” To sum up, what is needed is mindfulness, not just scientific data, for addressing pressing sustainability issues.

Mis-selling

Katarzyna Klimkiewicz

Faculty of Management, AGH University of
Science and Technology, Cracow, Poland

Synonyms

Financial mis-selling; Misleading sales; Unethical sales

Definition

Mis-selling is an unethical sales practice in which either a salesperson deliberately misrepresents a product or service to a customer or the particular offer is not suitable for the customer. The UK's former Financial Services Authority (FSA) describes mis-selling as "a failure to deliver fair outcomes for consumers" (Financial Services Authority 2006). Mis-selling may occur in case of flaws of product construction or as a result of the way the product/service is offered to the customer. From the CSR and corporate sustainability perspective, the attention should be given to possible adverse impact that businesses may cause for their stakeholders through mis-selling. This problem appears particularly often in products characterized by a high level of complexity that are sold by agents, rather than directly to the customer. The financial sector (including pensions, insurance policies, and mortgages) is reported as the one most often affected by mis-selling. Other sectors, where mis-selling may occur, include consumer electronics, auto repairs, and medical care.

Introduction

Since the financial crisis of 2008–2009, the debate on the proper sale of financial instruments has continued, with numerous studies demonstrating that, instead of operating efficiently, the financial sector has been imposing huge costs on the

economy (Wray 2011). Indeed, serious consequences of the improper sale of financial instruments can be observed as far back as the incident of mis-selling of personal pensions during 1988 and 1994 in the UK. These personal pension plans were introduced as part of a government campaign aimed at extending individual pension choice. The product, launched as a portable and flexible solution, relied upon the investment performance of its underlying funds. While considerable publicity was given to the advantages of this product, little attention was paid to the real comparison between personal pensions and existing final salaries in occupational pension plans (Ryley and Virgo 1999).

In a nutshell, approximately 2 million people (eligible for pensionable employment) may have been wrongly advised by life [insurance] companies and financial advisers to opt out, not join, or transfer benefits from existing occupational pension schemes in favour of personal pension plans. Most advisers involved in these transactions failed to give investors the investment business advice which was compliant with their obligations under the Financial Services Act 1986. As a result, the investors lost favorably defined benefits available in occupational pension schemes and ended up investing in an investment performance-related product which provided little security and no guaranteed benefits. (Ryley and Virgo 1999)

The second big mis-selling incident in the UK resulted from combining the sale of regular financial instruments, such as loans, credit cards, or mortgages with payment protection insurance (PPI). PPI was designed to cover repayments when people couldn't meet their obligations due to accident, illness, disability, or death. During the financial crisis of 2008–2009, it turned out that this insurance did not perform properly and, for many customers, turned out to be unnecessary. According to the Financial Conduct Authority (FCA), approximately 64 million PPI policies have been sold in the UK, mostly between 1990 and 2010. It is not clear how many of these policies were mis-sold. The FCA initially estimated that three million people could have been affected, and recent calculations show that more than £29 billion has already been paid back to people who complained about the sale of PPIs (Financial Conduct Authority 2017).

Inderst and Ottaviani (2009) cite a typical example of mis-selling as described in the code of conduct for the employees of a major bank in *Group Code of Conduct: Leading by Example*, Standard Chartered Bank, 2005:

Typically, mis-selling is associated with investment products when there may have been a failure to disclose all the associated risks or where an investment product is inappropriate to a customer’s needs. For example, a product with a long tenor [sic] (e.g., ten years) may have a guaranteed repayment of principal only on maturity date, but if prematurely liquidated it may not repay the full principal. This may result in mis-selling if it is sold to a customer who may have had a short term need for cash or to a customer who is 70 years old. (Inderst and Ottaviani 2009, p. 883)

The authors suggest that the cost of prospecting for customers (as perceived by the agent), the organization of the sales process, and the transparency of the commission structure influence the firm’s tolerance toward mis-selling. These examples show that misleading customers with incorrect information or the sale of improper products may impact not only one company but entire industries. From the perspective of corporate social responsibility and corporate sustainability, mis-selling is a result of an inappropriate policy adopted toward the most important stakeholder groups: employees and customers. Although mis-selling scandals are mostly discussed as incidents occurring in the financial sector, it is worthwhile analyzing the causes and consequences of mis-selling in broader terms and uncovering other critical incidents of misleading customers in diverse industries and organizations.

Forms of Mis-selling

Mis-selling occurs within the context of regulated markets (Benston 1998). While legal regulations set a framework for customer protection, specific organizational and cultural factors may lead to abuse and result in mis-selling.

Different types of mis-selling can be identified. Mis-selling may occur when the product is poorly designed or its core characteristics change after the sale, but the customer has either little or no possibility of cancelling the sale, or the cancellation is linked to a high liquidation fee. Mis-selling may also occur when a product is free from defects but is offered to a customer who doesn’t need it or who won’t properly benefit from the purchase. Different examples of mis-selling are shown in Table 1.

Mis-selling may be caused by several factors:

- 1. Misleading behavior of an employee. An employee deliberately misrepresents information, fails to describe key information about the product, provides misleading advice, or offers unsuitable products relative to expressed needs and preferences of customer. This may occur especially when employees are incentivized to sell particular products and control mechanisms are weak or there is silent acceptance of such practices.
- 2. Sales procedures providing non-customized advice. Conducting a need analysis, including assessment of the customer’s financial and personal risk preferences, is costly for banks; consequently, product or service advice is seldom

Mis-selling, Table 1 Examples of different types of mis-selling

The source of <i>mis-selling</i>	<i>Mis-selling</i> at the moment of sale	<i>Derivative mis-selling</i> (when the conditions of the agreement change)
Product characteristics	Product contains abuse clause	Some key characteristics of the product change and client has no possibility of negotiating a new agreement; cancellation is linked to a high liquidation fee
Service (the way of offering the product)	Cross-selling, bundled sale – customer needs to buy product B while buying product A Providing misleading information Concealing information	Information about the product doesn’t correspond to that provided in the agreement, delay in making decisions, lack of or slow reaction to consumer complaints, inconsistent communication

M

tailored to the needs of individual customers. Agents are incentivized to recommend products, although these products may not always be suited to the customer (Inderst and Ottaviani 2009). Often mis-selling cases result from a salesperson's unauthorized undertaking of an advisory role, when the agent is only qualified to provide product information. Other examples here might be cross-selling or a bundled-sell situation, when a particular product is sold only under the condition that the customer buys another, often less attractive one. For example, the condition for the customer to get credit is to buy dedicated payment protection insurance.

3. Misleading marketing activities. In this case of mis-selling, clients are attracted by some particular feature of the product; however, the nature of the product is different from its advertised features. For example, an advertisement for financial investing may be described as safe, when, in fact, the product should only be offered to customers interested in hazardous or risky investments. Misleading marketing activities also often include confusing or misleading information provided by sales agents determined to show the product or service in a positive light.
4. Single-track trainings. Organizations often provide trainings for employees on the features of new products. In the case of highly complex products, however, trainings may concentrate on the positive aspects of the product while neglecting or minimizing less favorable characteristics. Salespeople are led to believe that they possess all the necessary information to assist customers, when they actually only have partial knowledge of the product.
5. Complex product design or illegal selling practices. Some products are too complex to be understood by the average client. In this case, clients cannot identify the inherent risk factors that can lead to either no benefit or a loss to them (Franke et al. 2016). Additionally, there are also a number of documented cases of products offered for sale that included unlawful features, such as limited accountability of the provider, unjustified fees associated with

cancellation of the contract, and limitation of consumer rights. Regulatory agencies monitor the markets in order to identify these types of illegal practices, but the process of redressing these violations can take years. For some customers, staying in an unjust contract may result in serious emotional, health, and financial losses.

Mis-selling in the Banking and Insurance Sectors

Mis-selling is mostly discussed in the context of financial markets, particularly in the banking and insurance sectors (Ferran 2012). When the regulatory framework is poorly suited to the specific market conditions, embedding regulations within the organizational context may not be effective and won't protect customers from mis-selling practices. Selling and buying financial products takes place within the context of changing markets and consumer behavior (Harrison and Estelami 2015). The individualization of the decision-making process makes consumers take the responsibility for their own financial choices. Information asymmetry resulting from the highly **complex nature of products offered** in the financial services sector encourages customers who don't possess this specialized knowledge to use advisory services. According to a range of authors, product complexity is one of the factors that led to the mis-selling scandal in the UK (Black and Nobles 1998; Moore-Bick 2001; Ward 2000).

Black and Nobles (1998) describe additional factors that led to this situation, including regulatory novelty, political ideology, and industry dynamics. In the opinion of the authors, the case of pension mis-selling cannot be regarded as an unrepeatable episode, as it was a result of **regulatory blindness**. The authors note that the quality of training aimed at increasing the competence of the advisors could not be effective, due to high levels of employee turnover in the life insurance industry and the specific remuneration structure. In fact, the training was costly for firms and advisors didn't spend much time on it. Sales agents were mostly self-employed and paid on a commission basis only.

In this case, the role of financial advisors may be likened to that of a regular salesforce who are incentivized to provide information to customers based on a sale's metrics. A visible agency conflict appears, then, when advisors are well paid by the organization (e.g., receive large bonuses) to sell low-quality products. In this case, the individual interests of the advisor may be aligned with the company's interests; however, this will be contrary to the best interests of the customer.

In the UK pension scandal, customers chose to give up their rights to belong to occupational pension plans in exchange for personal pension plans, because this offer was presented as a favorable option. In reality, this decision was unprofitable for them. They trusted that the advice they had been given was impartial and in line with their interests. This demonstrates the crucial role of **professional advisors** in the financial investment process (Aldridge 1998). In summary, agents who are encouraged to sell products, regardless of their fit with customer expectations and needs, misuse their authority and expertise, a practice that leads often to mis-selling.

Mis-selling and Corporate Culture

Through performance of everyday duties, sales agents contribute to and reflect the corporate culture (Brannan 2017). A number of reports stress the controversial role of a sales-based culture that exerts pressure on employees, which may lead to counterproductive employee behaviors (Lindley 2014; Sedgwick 2017). For example, Seal and Ye (2014) describe an example of a major bank where the Balanced Score Card (BSC) changed actor perceptions and actions and led to mis-selling. According to the authors, "The BSC may have improved organizational coordination but long-standing values based on a bonus culture contributed to long-term commercial problems. Introducing BSC's impact on organizational success/failure was ambiguous" (Seal and Ye 2014, p. 466).

The culture of an organization is spread through both written and unwritten rules and

practices. When new employees are taught how to circumvent the rules for short-term profits and observe more experienced colleagues also acting in this fashion, they learn that this kind of misleading behavior is informally accepted. If this is reflected in, for example, human resource policies, training, and remuneration, it shows that fair treatment of customers is not embedded in the organizational culture (Financial Services Authority 2006). Based on regulatory work and assessment, FSA identifies the central causes of unfair treatment of consumers:

- Low significance of "fair treatment of customers" in the corporate culture.
- Shortcomings in product design.
- Products/services targeted to customers contrary to their actual needs or possible investment horizons.
- Unclear or improper information provided before, during, or after the point of sale.
- Products perform differently from what the organization led customers to expect.
- Customers are advised inappropriately regarding the nature and performance of products.
- Post-sale barriers exist for changing the product, switching providers, submitting a claim, or making a complaint (Financial Services Authority 2006).

Both practitioners and researchers suggest that firms that sell through agents need to comply with internal standards and assure that these standards don't cause bias (Inderst 2010). It is suggested that organizations work at developing a so-called service culture that aims at serving the client instead of the organization itself (Sedgwick 2017). This should help sustain the employee, client, and organizational relationship. Stephen Sedgwick (2017) formulates 21 recommendations for banks. These recommendations are basically oriented toward rethinking and reconstructing variable reward payments and eliminating incentives directly linked to sales or the achievement of sales targets. Additionally, according to the author, the bank should "formally examine its workplace culture and institute formal processes to redress any conscious or unconscious bias towards sales in

reference to ethical behavior and customer service” (Sedgwick 2017, p. 9).

Costs of Mis-selling

Numerous studies show the highly negative impact that mis-selling creates among branches and their stakeholders. Mis-selling is not limited to the financial sector; therefore, its incidence should be monitored and given careful attention in all sectors. CSR and corporate sustainability researchers should give more attention to possible adverse impacts that businesses may cause for their stakeholders through mis-selling. These practices pose serious implications for firms, as misleading consumers may be fined by regulatory agencies in addition to organizations losing credibility in the marketplace (Armour et al. 2017; Karpoff et al. 2005). As reported by the Boston Consulting Group (2017), between 2009 and 2016, US regulators collected USD 179 billion in penalties from banks, while European regulators collected only USD 20 billion for the same period (Grasshoff et al. 2017). Following Carletti (2017), “the Consumer Financial Protection Bureau (CFPB) was created in the aftermath of the financial crisis and authorized under the Dodd Frank Act of 2011. In 2016, CFPB’s supervisory and enforcement actions resulted in financial institutions providing more than USD 58 million in redress to over 516,000 consumers and orders through enforcement efforts for approximately USD 247 million in total relief for consumers who fell victim to various violations of consumer financial protection laws, along with over USD 83.7 million in civil money penalties, used to compensate the consumers” (Carletti 2017, p. 12). The costs of mis-selling fall not only as penalties on customers or firms. There are also regulatory costs (and charges on financial service firms) and other unintended consequences. According to the FCA, while providing regulatory interventions (aimed at preventing development or sales of unsuitable products, risk may occur that will discourage consumer-oriented innovations, as firms might be reluctant to introduce new products or (be) unwilling or unable

to enter a market (Financial Conduct Authority & Financial Ombudsman Service 2016).

Mis-selling Regulation and Prevention

Since the UK pension mis-selling scandal and subsequent incidents, regulators have worked to find ways to limit the occurrence of such practices. As stated in the study on mis-selling of financial products, *Marketing, Sale and Distribution*, requested by the ECON committee, before the financial crisis of 2007–2008, regulators of financial markets had no constraints regarding selling processes or on the design and distribution of financial products. Additionally, institutional investors failed to understand and properly assess the risks associated with complex financial products. In some cases, the recommendation was very general: all marketing communication should be fair, clear, and not misleading. In 2011, the European Commission concluded that “systematic mis-selling of financial products by financial institutions and the massive losses of institutional and retail investors could be attributed to inadequate disclosure of the underlying costs, charges and risks of products and the incentives of firms to design unsuitable products for their customers, and customers’ behavioral biases and financial illiteracy” (Alexander 2018, p. 5). A recent study by Stolper (2018) suggests that increasing “financial literacy leads to a higher confidence in one’s own judgment and prompts individuals to use financial advice as just another source of information they process when making their financial decisions” (Stolper 2018, p. 295).

Before the financial crisis of 2008–2009, the dominating paradigm of the EU Regulatory Framework was based on disclosure – policymakers assumed that disclosing relevant information to investors and customers would assure efficient and socially optimal decisions on the financial market. In fact, the financial collapse has shown that the regulatory disclosures were inadequate instruments that didn’t eliminate conflicts of interest arising from

information asymmetry and complexity. Consequently, the Market in Financial Instruments Directive II – Directive 2014/65/EU (European Commission 2014) – was introduced, the most significant EU legislation regarding the reform of marketing, sale, and distribution of financial products. MiFID II is aimed at establishing rules concerning conflict of interests and disclosure of costs that may fall on the consumer.

MiFID II indicates a set of requirements that financial institutions should introduce in order to strengthen customer protection, by reducing the effects of information asymmetry arising from financial literacy, market expertise, and

bargaining power. To mitigate these risks, financial institutions should provide continuous assessment of their policies, procedures, and practices, as well as the quality and effects of the advice provided by employees. Based on the MiFID II (Directive 2014/65/EU) directives, four main areas of regulations and assessment should be monitored and improved (Fig. 1).

- Corporate governance provides rules and structures for insuring that decisions made by directors, managers, and employees will be aligned with the customer's best interests (European Commission 2014).

Mis-selling, Fig. 1 Overview of mis-selling regulations

- Corporate culture should be oriented toward customer's best interests. Agents should be encouraged to increase their efforts while serving customers. This includes possessing necessary knowledge and competence, obtaining information about client's preferences, informing customers about potential risks, and reporting to clients about suitability and appropriateness of products and services (Lindley 2014; Sedgwick 2017).
- Product risk management. According to MiFID II, financial institutions are obliged to constantly monitor the approval process for each financial product. This process should include targeting specific groups of customers and assessing relevant risks. The reporting rules on the appropriateness of the products give the regulator more power to intervene at the stage of product design. Disclosure rules require financial firms to disclose possible conflicts of interest and provide more transparent information about products, such as requirements on products and costs, fees and commissions, and costs and risks in selling bundles of financial products (European Commission 2014; Franke et al. 2016).
- People risk management is aimed at continuous assessment of remuneration and performance measurement systems in order to identify and eliminate possible cognitive biases and different types of rationalizations which may encourage agents to misleading behavior (Blacker and McConnell 2015).

MiFID II is directed toward improving the mechanisms of consumer protection; however, it has also encountered criticism. Alexander (2018) points out that MiFID II raises concerns about segmentation and regulatory arbitrage, as it doesn't apply to financial instruments regulated by insurance supervisors or covered by other EU legislation (Alexander 2018). Other unintended effects of MiFID II may occur as banks may be discouraged from providing services to certain groups of customers, as the protection mechanisms will increase costs and serving these customers will become unprofitable for the bank (Franke et al. 2016).

Summary

Mis-selling is an unethical sales practice in which either a salesperson deliberately misrepresents a product or service to a customer or the particular offer is not suitable for the customer. Mis-selling is not simply a case of providing misleading information. It happens that customers are tempted, misunderstand the information provided by advisors, or rely too much on the positive aspects of a product while neglecting the risks. The financial sector is reported as the one most often affected by mis-selling. An adequate level of financial literacy is crucial for profiting from financial advice; therefore, all parties as customers, regulators, and firms should be interested in increasing financial literacy, so that customers can make independent decisions aligned with their interests.

Definition

Modeling sustainability involves using mathematical and computational methods to simulate and analyze various aspects of sustainability. This includes resource use, environmental impacts, social and economic systems, and their interactions and interdependencies. The purpose of sustainability modeling is to help decision-makers understand and evaluate the potential consequences of different actions and policies and to support the development of sustainable solutions.

Examples of sustainability modeling include life cycle assessment (LCA) models, which are used to assess the environmental impact of a product, process, or system over its entire life cycle. Energy systems models are used to analyze a region's energy demand and supply, taking into account factors such as energy efficiency, renewable energy sources, and emissions. Social-ecological models are used to analyze the interplay between social and ecological systems and to assess the impact of human activities on the environment.

Climate change models are used to simulate the Earth's climate system and assess the impact of human activities on the climate. These models also evaluate the potential consequences of different mitigation and adaptation strategies. Finally, water resource management models are used to optimize the allocation of water resources for different uses. This involves considering factors such as water availability, quality, and demand.

Introduction

In recent years, there has been an increased focus on the concept of sustainability, which is

multifaceted and intricate. Sustainability involves striking a balance between economic growth, social development, and environmental protection, all with the overarching goal of fulfilling the needs of the present generation while ensuring that future generations can meet their needs without difficulty. Successfully tackling sustainability challenges necessitates a comprehensive and interdisciplinary approach, with modeling playing a significant role in this process.

In the context of sustainability, modeling is a valuable tool that can be employed to scrutinize, comprehend, and anticipate the behavior of complex systems. These models can be used to analyze the various interactions between the environment, economy, and society while also predicting the effects of different policies and actions on these systems. Application of modeling in the sustainability realm can yield valuable insights, such as recognizing the primary drivers behind environmental deterioration, evaluating the effects of different policy alternatives, and determining the trade-offs and synergies between various sustainability objectives.

One of the leading sustainability challenges that models can help to address is climate change. The Intergovernmental Panel on Climate Change (IPCC) has provided clear evidence that human activities are causing unprecedented warming of the Earth's surface, with potentially severe consequences for ecosystems and human societies (IPCC 2018). Models can be used to predict climate change's future impacts and assess the effectiveness of different mitigation and adaptation strategies. For instance, integrated assessment models (IAMs) have been widely used to assess the impact of different policy scenarios on future emissions and to evaluate the potential costs and benefits of different mitigation options (Nordhaus 2017).

The depletion of natural resources is a significant sustainability challenge that can be analyzed using models. Models can examine the interactions between resource extraction, economic growth, and environmental degradation and evaluate the impact of various resource management policies (Feng et al. 2019). Bioeconomic models have been developed to analyze the trade-offs between economic growth, resource depletion, and environmental impacts. Similarly, social dimensions such

as poverty and inequality are also a part of sustainability. Models can be employed to assess the interactions between economic growth, poverty, and inequality and to evaluate the impacts of different social policies. For instance, microsimulation models have been developed to analyze the impact of social policies on poverty and inequality (Erreygers and Vanhuysse 2017).

Integrated assessment models (IAMs) are commonly used in sustainability research. IAMs are designed to integrate multiple sustainability dimensions and to examine the interactions between different components of the environment, economy, and society. They can evaluate the impacts of various policy options and identify trade-offs and synergies between different sustainability goals. The Integrated Assessment Model (IAM) developed by the Intergovernmental Panel on Climate Change (IPCC) is widely used to evaluate the potential costs and benefits of different policy scenarios (IPCC 2014).

Models play a crucial role in understanding and addressing sustainability challenges by providing valuable insights such as identifying the key drivers of environmental degradation, assessing the impacts of different policy options, and identifying trade-offs and synergies between different sustainability goals (Keppo et al. 2021; Workman et al. 2021).

Types of Sustainability Models

Sustainability research encompasses a wide range of disciplines and perspectives, and as such, various models are used to study different aspects of

sustainability. These models can be broadly categorized into three main types: ecological, economic, and social (Table 1).

Ecological models are used to analyze the interactions between human activities and the natural environment. These models can be used to study issues such as biodiversity loss, habitat destruction, and climate change. Examples of ecological models include biogeochemical models, ecosystem models, and climate models. For instance, the dynamic global vegetation model (DGVM) is a biogeochemical model that simulates the interactions between vegetation, soil, and climate to understand how land use and climate changes affect the carbon cycle and biodiversity (Jose et al. 2023; Bonan 2019; Martens et al. 2021).

Economic models analyze the interactions between economic activities and the natural environment. These models can be used to study issues such as resource depletion, economic growth, and environmental degradation. Examples of economic models include integrated assessment models, bioeconomic models, and microsimulation models. For instance, the integrated assessment model (IAM) is a type of economic model that integrates different models, such as climate models, economic models, and land-use models, to comprehensively analyze the different factors that shape sustainability outcomes (Nordhaus 2017).

Social models are used to analyze the social interactions that shape sustainability outcomes. These models can be used to study issues such as social inequality, poverty, and social network dynamics. Examples of social models include

Modeling in Sustainability, Table 1 Different types of models used in sustainability research

Model type	Examples	Applications	Model name
Ecological models	Ecosystem models, biogeochemical models	Analyzing the impacts of different management options on ecosystems	Dynamic global vegetation model (DGVM)
Economic models	Integrated assessment models, bioeconomic models, microsimulation models	Analyzing the interactions between resource extraction, economic growth, and environmental degradation, assessing the impacts of different policy options on poverty and inequality	Integrated assessment model (IAM)
Social models	Social network analysis, agent-based models	Analyzing the impacts of social interactions on sustainability outcomes	Agent-based model (ABM)

social network analysis and agent-based models. For instance, the agent-based model (ABM) is a type of social model that simulates the interactions between agents (e.g., individuals, households, and firms) to understand how social interactions shape sustainability outcomes (Axelrod 1997; Kozitsin 2022).

Apart from the abovementioned categories, models can also be classified as quantitative or qualitative (Table 2). Quantitative models are numerical models that use mathematical equations to represent relationships and make predictions. Qualitative models, on the other hand, use verbal or graphical representations to describe relationships and make predictions (Chi 1997). The choice of model will depend on the specific research question and the type of data available, and each type of model has its strengths and limitations.

One example of a quantitative model in sustainability research is the dynamic integrated model of climate and the economy (DICE) model developed by William Nordhaus (2017). The DICE model is an integrated assessment model (IAM) that integrates ecological and economic models to comprehensively analyze sustainability outcomes. The model is used to study policy interventions' impacts and assess the trade-offs between different sustainability objectives.

On the other hand, qualitative models are more suitable for capturing complex social interactions and subjective experiences. An example of a qualitative model in sustainability research is the integrated model to assess the global environment (IMAGE) model developed by the PBL

Netherlands Environmental Assessment Agency (De Vries and Petersen 2009; Stehfest et al. 2014). The IMAGES model comprehensively analyzes the different factors that shape sustainability outcomes, including climate, economy, and land-use.

IAMs, such as the DICE and IMAGE models, combine quantitative and qualitative elements. These models comprehensively analyze sustainability outcomes by integrating ecological, economic, and social models (Stehfest et al. 2014).

Approaches and Methodologies in Sustainability Modeling

Sustainability modeling is an interdisciplinary field that integrates various approaches and methodologies to analyze complex sustainability issues. The most common approaches used in sustainability modelling include systems thinking, life cycle assessment, and input–output analysis (Table 3). This section will provide an overview of these approaches and their applications in sustainability modeling.

Systems Thinking

Systems thinking is a holistic approach that considers the interconnectedness of different components in a system and how they interact with each other to produce a specific outcome. This approach is commonly used in sustainability modeling to understand the interplay between sustainability's ecological, economic, and social dimensions (Marten 2012). For instance, systems thinking can help identify the interdependence

Modeling in Sustainability, Table 2 Comparison of quantitative and qualitative models in sustainability research

Type of model	Strengths	Limitations
Quantitative models	Make precise predictions suitable for testing hypotheses based on quantifiable data	Limited in application if data is inadequate or unreliable. May not be understandable for nontechnical audiences
Qualitative models	It can capture complex social interactions and subjective experiences and be easily understood by nontechnical audiences	They may not be useful in making precise predictions, may not be as scientifically rigorous as quantitative models, and may not be suitable for testing hypotheses

(Axelrod 1997; Kozitsin 2022; Hulme 2007).

Modeling in Sustainability, Table 3 Overview of different approaches and methodologies used in sustainability modeling

Approach/ methodology	Description	Applications in sustainability modeling	Advantages	Limitations	Examples
Systems thinking	An interdisciplinary approach that views the world as a complex system of interconnected elements and seeks to understand the interactions between these elements in order to have a better and clearer perspective of the system as a whole better	Assessment of the interplay between sustainability's ecological, economic, and social dimensions	Offers a comprehensive view of sustainability, considering multiple perspectives and factors	It can be complex and challenging to understand, especially for nonexperts	STELLA (Systems Thinking, Experimental Learning Laboratory with Animation), Vensim, System Dynamics
Life cycle assessment (LCA)	A method used to assess the environmental impact of a product, process, or activity from the cradle to the grave. LCA considers the entire life cycle of a product, from raw material extraction to disposal	Evaluates the environmental impacts of a product or system	Provides a comprehensive view of the environmental impacts of a product or service	It can be time-consuming and resource-intensive to implement	GaBi, SimaPro, OpenLCA
Input–output analysis	A method used to analyze the interdependencies between different economic sectors in order to understand the flow of goods and services between them		Offers a comprehensive view of the economic impacts of sustainability issues	Limited in its ability to consider social impacts	MRIO (multiregional input–output) models, WIOD (World Input–Output Database)
Integrated assessment models (IAMs)	Models that combine various approaches and methodologies to provide a comprehensive understanding of sustainability issues. IAMs typically include ecological, economic, and social models and seek to understand these dimensions' interactions.	A modeling approach that integrates data from multiple sources to provide a comprehensive view of sustainability issues. IAMs combine economic, ecological, and social data to analyze complex sustainability challenges like climate change and energy systems			DICE (dynamic integrated climate-economy), PAGE (Policy Analysis of the greenhouse effect), IMAGE (integrated assessment model)

between the economy and the environment and how changes in one system can impact the other.

Systems thinking provides a valuable framework for analyzing sustainability problems, as it helps identify interdependencies between different system components (Senge 1990). For instance, in the context of climate change, systems thinking can help to understand the interrelationships between the emission of greenhouse gases, the impacts of climate change on ecosystems, and the socio-economic impacts of these changes.

Life Cycle Assessment

Life cycle assessment (LCA) is a methodology that assesses the environmental impacts of a product, service, or system throughout its entire life cycle. This includes the extraction of raw materials, production, transportation, use, and disposal of the product (ISO 2006a, 2006b). LCA provides a comprehensive understanding of the environmental impacts of a product or system and can be used to identify areas for improvement in terms of sustainability.

For instance, an LCA of a vehicle might consider the environmental impact of the vehicle's production, use, and disposal at the end of its life cycle. The results of an LCA can inform decision-making related to sustainability, for example, by identifying areas where improvements can be made to reduce the environmental impact of a product or service (Buxel et al. 2015).

Input–Output Analysis

Input–output analysis is an economic methodology that analyzes the interdependence between different sectors of an economy. This approach is commonly used to assess the impact of changes in one sector on the rest of the economy and to understand the flow of goods and services between different sectors. For instance, input–output analysis can be used to assess the impact of changes in the energy sector on the rest of the economy, and to identify opportunities for reducing greenhouse gas emissions (Igos et al. 2015; Minx et al. 2009).

Integrated Assessment Models

Integrated assessment models (IAMs) integrate multiple dimensions of sustainability, including the ecological, economic, and social perspectives. IAMs are used to analyze complex sustainability issues, such as climate change, and to provide policy recommendations for addressing these issues. IAMs are commonly used to analyze the trade-offs between economic growth and environmental protection and identify sustainable development opportunities (van Soest et al. 2019).

The Importance of Combining Quantitative and Qualitative Models

While quantitative models provide valuable insights into the underlying mechanisms of sustainability issues, they cannot often capture the complexity and uncertainties inherent in sustainability issues (Ascough Ii et al. 2008). On the other hand, qualitative models provide a more comprehensive understanding of the social and cultural factors that influence sustainability issues, but they need more precision than quantitative models (Di Vaio et al. 2020). Thus, it is essential to use a combination of quantitative and qualitative models to provide a comprehensive understanding of sustainability issues. This can be achieved by incorporating qualitative models into quantitative models or using a multicriteria decision analysis approach that combines quantitative and qualitative data.

Applications in Practice

Sustainability models are applied in various sectors, scales, and issues. This section focuses on the practical use of sustainability models in different application areas, including energy systems modeling, urban sustainability planning, and climate change impact assessment.

Energy System Modeling

Energy system modeling is widely used to analyze and optimize energy systems. Energy system

modeling aims to assess the feasibility, sustainability, and environmental impact of different energy systems, such as renewable energy systems and fossil fuel systems. Energy system models evaluate the technical, economic, and environmental performance of different energy systems and determine the optimal combination of energy sources and technologies that sustainably meet the energy demand.

Examples of energy system models include the market and allocation (MARKAL) model, the integrated MARKAL-EFOM system (TIMES) model, and the long-range energy alternatives planning (LEAP) model (Bhattacharyya and Timilsina 2010; Perwez et al. 2015; Perissi et al. 2021). The MARKAL model is widely used to evaluate the long-term energy and environmental implications of different energy policies and scenarios. The TIMES model is a linear programming model that optimizes the energy supply and demand for different energy systems (Lopion et al. 2019). The LEAP model is a comprehensive energy and emissions planning tool that helps policymakers, planners, and researchers analyze energy systems and their environmental impact (Perwez et al. 2015).

Urban Sustainability Planning

Urban sustainability planning is an essential application of sustainability models in urban planning and development. Urban sustainability models evaluate the sustainability of different urban development scenarios and determine the optimal combination of land use, transportation, and energy systems that support sustainable urban development (Liu 2008).

Climate Change Impact Assessment

Climate change impact assessment is another important application of sustainability models. Climate change impact models are used to assess the potential impacts of climate change on various systems and sectors, such as agriculture, water resources, health, and coastal zones. These models are used to develop adaptation and mitigation strategies to reduce climate change's impacts and support sustainable development (IPCC 2014).

Benefits of Using a Combination of Models

Using quantitative and qualitative models provides a comprehensive understanding of sustainability issues. Quantitative models provide numerical results and rigorous analysis, while qualitative models provide insights into sustainability's subjective and social aspects. Using both models allows a more comprehensive and integrated analysis of sustainability issues, providing a more comprehensive picture of the complexities and interrelationships of sustainability problems (IPCC 2014).

Energy system modelling: This type of model is used to analyze energy systems and their interactions with the environment and society, including the assessment of energy supply, demand, and sustainability. Examples of energy systems models include the EnergyPLAN model, which is used to evaluate the impact of renewable energy policies on energy systems, and the MARKAL model, which is used to optimize energy systems based on cost-effectiveness (Ma et al. 2018; Lund et al. 2017).

Urban sustainability planning models: They are used to analyze urban sustainability, including land use, transportation, and energy systems, to support decision-making in urban planning. For instance, the system for urban stormwater treatment and analysis integration (SUSTAIN) model evaluates the sustainability of different city land use and transportation scenarios (Lovell 2010).

Climate change impact assessment models are used to assess the impacts of climate change on various sectors, including agriculture, water resources, and coastal zones (Erda et al. 2007). Examples of climate change impact models include the DIVA model, which is used to assess the impacts of sea level rise on coastal zones, and the Impacts 08 model, which is used to assess the impacts of climate change on agriculture.

These are just a few examples of the different types of models used in sustainability research. It is important to note that the use of multiple models, both quantitative and qualitative, can provide a more comprehensive understanding of sustainability issues in different application areas.

Limitations and Challenges

Sustainability modeling also faces several limitations and challenges that must be addressed for the models to be effective and reliable. This includes the following as shown in Table 4.

Data Availability

Data are the foundation of any model and are essential for the accuracy and reliability of the results. However, data availability and quality can be significant challenges in sustainability modeling. In some cases, data may not be available, while in others, the data may need better quality. For instance, emissions and energy consumption data are only sometimes readily available or accurate, especially in developing countries (Ma et al. 2019). This can result in the need for more information to support decision-making, making it difficult to assess the sustainability of a particular system.

Model Complexity

Sustainability models are often complex and interdisciplinary, making them challenging to develop, understand, and use. Model complexity can result from the number of variables, the interactions between these variables, and the methods used to

represent these variables and interactions. For instance, some models may include many components, such as energy, economic, and environmental systems. It can be challenging to accurately represent the interactions between these components (Baartman et al. 2020).

Uncertainty

Uncertainty is a natural aspect of sustainability modeling, given that the data used in models are often uncertain, and the models themselves may have inherent limitations. For instance, the assumptions made in models about future trends and developments, such as future energy demand, can be uncertain (Blair et al. 2019). This uncertainty can affect the accuracy and reliability of the model results and can also impact the decision-making process.

Model Evaluation and Validation

Model evaluation and validation are essential steps in the modeling process, as they ensure that the models are reliable and accurate. However, evaluating and validating sustainability models can be challenging, as the models may include complex interrelationships and multiple components, making it difficult to determine their validity and accuracy (IPCC 2014).

Model Integration

Model integration is the process of combining multiple models to create a comprehensive understanding of sustainability issues. However, integrating different models can be challenging, as the models may use different methods and assumptions, leading to inconsistencies in the results (Wang et al. 2019).

Communication of Model Results

Finally, communicating the results of sustainability models to stakeholders can also be challenging, as the results may be complex and technical, making it difficult for stakeholders to understand and use them effectively. This is particularly true for stakeholders who need to become more familiar with the technical aspects of sustainability modeling (Elsawah et al. 2019).

Modeling in Sustainability, Table 4 Summary of limitations and challenges in sustainability modeling

Limitation/ challenge	Description
Data availability	Lack of data or poor-quality data affects the accuracy and reliability of the results
Model complexity	Complex interdisciplinary models can be challenging to develop, understand, and use
Uncertainty	Uncertainty affects the accuracy and reliability of the results and can impact the decision-making process
Model evaluation and validation	Evaluating and validating complex models can be challenging
Model integration	Integrating different models can be demanding due to inconsistent methods and assumptions

Case Studies of Sustainability Modeling in Practice

1. **Environmental management:** In environmental management, sustainability models have been used to predict the impacts of land use change on biodiversity and ecosystem services. For instance, the integrated assessment model (IAM) has been used to assess the impacts of climate change on biodiversity and the provision of ecosystem services (Van Soest et al. 2019; Daioglou et al. 2019).
2. **Urban planning:** In urban planning, sustainability models have been used to assess the potential impacts of proposed urban development projects on the environment, including air and water quality, land use, and energy use (Bibri et al. 2020).
3. **Resource management:** In resource management, sustainability models have been used to assess the sustainability of various resources, including water, energy, and food (Namany et al. 2019). For instance, the water evaluation and planning (WEAP) system has been used to assess water sustainability in various regions and to support decision-making related to water management (Pallavi et al. 2021).

Future Directions and Advancements

Sustainability modeling has come a long way since its inception, and several avenues for future research have the potential to advance the field significantly. This section will discuss some of the most promising future directions for sustainability modeling research.

Advancements in Computational Methods

One of the biggest challenges in sustainability modelling is the sheer complexity of the systems being studied. As sustainability modeling evolves, computational methods will likely play a significant role in advancing the field. Advances in high-performance computing, such as the development of cloud computing and supercomputing platforms, will allow for more

complex and sophisticated models to be developed and run. Additionally, developing new algorithms and optimization techniques, such as machine learning and artificial intelligence methods, will help improve the accuracy and robustness of sustainability models.

Data Availability and Integration

Another critical aspect of sustainability modeling is the availability and quality of data. To be applicable, sustainability models must be based on accurate and comprehensive data, including historical and real-time data. Data availability and quality are expected to improve in the coming years as more sensors and monitoring systems are deployed, and data sharing and integration become more common. Integrating remote sensing data, such as satellite imagery and atmospheric measurements, will significantly advance sustainability modeling.

Interdisciplinary Collaborations

Sustainability is a complex and multidisciplinary field, and sustainable development requires collaboration between various sectors and stakeholders. Therefore, future research in sustainability modelling must be interdisciplinary, bringing together experts from various fields, including computer science, engineering, ecology, economics, and social sciences. Interdisciplinary collaborations will be essential for developing integrated models that consider the complex interactions between different system components and provide a more comprehensive picture of sustainability.

Integration of Artificial Intelligence and Machine Learning Techniques

Artificial intelligence and machine learning techniques have the potential to revolutionize sustainability modeling. These techniques can be used to automate the model development process, making it faster, more accurate, and less expensive. For instance, machine learning algorithms can automatically identify the most critical parameters and variables in a system, optimize model parameters, or predict future trends and patterns. In the coming years, artificial intelligence and machine learning

techniques will likely play an increasingly important role in sustainability modeling.

Integration of Participatory and Stakeholder-Engaged Approaches

Finally, future research in sustainability modeling must be participatory and stakeholder-engaged, considering the perspectives and needs of different groups and individuals. This requires the development of models that are transparent, accessible, and easy to use and that provide stakeholders with the information they need to make informed decisions. In addition, integrating participatory and stakeholder-engaged approaches into sustainability modeling will help ensure that models are relevant, trustworthy, and useful for decision-making.

Sustainability modeling is an evolving field with numerous future research and advancement opportunities. By addressing the limitations and challenges of the field and continuing to develop and integrate new methods and techniques, sustainability modeling can significantly contribute to sustainable development in the coming years.

Summary

Sustainability modeling is a critical tool for addressing complex sustainability challenges today. Integrating quantitative and qualitative models provides a comprehensive and holistic approach to modeling sustainability, considering various aspects of environmental, social, and economic sustainability.

Throughout this paper, the importance of sustainability modeling has been emphasized, including advances in computational methods, data availability and integration, interdisciplinary collaborations, integration of artificial intelligence and machine learning techniques, and the integration of participatory and stakeholder-engaged approaches. These developments have led to a growing awareness of the need for an integrated and holistic approach to sustainability modeling, focusing on data-driven decision-making and model evaluation and validation.

It is important to note that despite advances in sustainability modeling, many limitations and challenges still need to be addressed. However, with continued research and advancements in the field, sustainability modeling will continue to play a crucial role in addressing current and future sustainability challenges.

In conclusion, sustainability modeling has the potential to have a significant impact on the way we understand and address sustainability challenges. We must continue to invest in its development and improvement.

Models of Innovation

► Sustainable and Innovation Process

Modern Corporation and Private Property, The

Min Yan
Queen Mary University of London,
London, UK

Introduction

The Modern Corporation and Private Property is one of the most influential books in the business history of the United States. It is written by Adolf A. Berle and Gardiner C. Means in the 1930s and remains of central value to those studying or researching corporate evolution. It is a foundational text in company law and corporate governance, and many of today's theoretical debates about corporate governance structure are directed, or at least substantially affected, by the core theses of Berle and Means's monumental work.

The book presents a substantial, revolutionary view of the modern corporate system and the related economic concepts. However, the authors' anti-neoclassical economic stance was largely influenced by the institutional economists such as William Ripley (1867–1941), Thorstein Veblen (1857–1929), Wesley Mitchell (1874–1948), and Rexford Tugwell (1891–1979), who focus on the important role of institutions in affecting economic behaviour. On top of that, the authors were indebted to Professor Edwin F. Gay, the founding Dean of Harvard Business School, who acted on the recommendation that research should be done on contemporary corporate development.

Traditionally, companies or corporations were merely a legal device for carrying on the business owned by an individual or a small group of people, and these private enterprises were usually under the direct management of their owner. As a consequence, the self-interest of the property owner was regarded as the best assurance of economic efficiency, as it was in the owner's best interests to run his business effectively in order to maximize profits. The dominant views about private property, profit motive, and wealth, among other foundational economic concepts at that time, were all established on the combination of ownership and control of private property advocated by Adam Smith (1982) and his followers.

Berle and Means, however, argued that the power of control over wealth could be decoupled from ownership by distinguishing “passive property” and “active property.” In other words, the control of physical assets is transferred to others, usually managers of directed companies, from the individual owners, who still retain the proprietary interests in it. The theory put forward by this book challenges the orthodoxy of the nineteenth and early twentieth centuries. The new developments relating to the concentration of economic power, the dispersal of stock ownership, and the separation of ownership and control, as identified by the authors, all served to undermine the conventional viewpoint.

When ownership is separated from control, the divergence of interests between the shareholders and the management becomes inevitable. Managers and directors who make profits by

operating the company successfully cannot be entitled to the fruits since they are just employed by the owner/shareholders and thereby have no proprietary right over the assets. Even if they are able to share in its profits by possessing some stocks in the company, the motive of self-interest – which operated smoothly in the context of traditional private enterprises – is not enough to stimulate the managers to contribute their whole effort. This is because they will not receive a proportionate benefit from the company's success as 'proprietary owner'. Also, the diffused ownership makes it more difficult to supervise and monitor those in control. All these changes were identified by the authors and constitute the subject of their book.

Intellectual Framework

The Modern Corporation and Private Property is uniquely a collaboration of a lawyer and an economist. The key concept of concentration of economic power in the hands of a few large companies, in particular a few hundred active managers of these companies, is obtained through Gardiner Means's statistical analysis of the 200 largest non-financial companies. This economic part of the book also indicates a continuing increase in the aggregation of wealth by these companies and the dispersion of the stock ownership. Another key concept, the separation of ownership and control, is arrived at by the legal analysis of Adolf Berle, who tracks the evolution of the American company from traditional private enterprise to the modern corporate form. Specifically, he examines the ever-growing discretionary power of managers. Managers who are in executive control, including directors of the board as well as corporate executives and officers, could obtain increasing power by creating or altering the participating rights of various classes of shares, utilizing paid-in surplus and stock purchase warrants, changing the original contract rights, and manipulating the earnings of others to accelerate the separation between ownership and control.

The ideas elaborated by Berle and Means can be traced back to the work of Thorstein Veblen (1899, 1914, 1919, 1921, 1923). Thomas Carver's *The Present Economic Revolution in the United States* (1925) and William Ripley's *Main Street and Wall Street* (1927) could also be seen as embryonic, as the trends of increased distribution of corporate securities and some disenfranchisement of shareholders are raised respectively by each book. In effect, *The Modern Corporation and Private Property* also develops Means's own early statistical studies (Berle and Means 1930; Means 1930, 1931a, b, c) and Berle's contemporary contribution on the devices for diluting stock participation rights and the doctrine of corporate powers in trust (Berle 1930, 1931).

The mainstream economic theories at that time were established on the basic assumption that rational entrepreneurs would maximize profits. Nevertheless, the increasing discrepancy between the legal-economic theory and economic fact (actual business practice) attracted the attention of many scholars, who then sought to address it. The study of the separation of ownership and control in the modern company can be regarded as the climax to the research that preceded it (Isaacs 1933). Berle and Means question the traditional logic of private property and profits; trace and discuss the changes the modern corporations have brought in; and finally convince us that the separation of control and ownership is an inevitable trend caused by the growth of modern companies, and an enormous advantage; but that at the same time, many of the previous checks for management have become ineffective due to those changes. The authors present a new economic epoch for us and set the theoretical basis for later research in the field.

Core Concept

Corporate changes, including the concentration of economic power in a few large modern companies and the divorce of control from ownership, mean that the traditional theories regarding property and other classical economic concepts are no longer applicable. After resolving whether or not such

a phenomenon is irreversible and enduring, the principal subject of *The Modern Corporation and Private Property* is the impact of separation between ownership and control. For example, can shareholders who surrender control to managers protect themselves to the same extent as the owner who exercises control over his/her wealth, and what does the new property right imply?

The rapid and extensive concentration of economic power within the modern corporate form, particularly the few largest companies, and the separation of the two classical characteristics of ownership – risking collective wealth in profit-seeking enterprise and management of responsibility for that enterprise – indicate that the time is ripe to reappraise the applicability of the conventional economic concepts. If the traditional logic of private property and profits does not fit the new situation any longer, certain concepts in the realm of classic capitalism need to be modified or even discarded. The new picture of economic life as well as the emerging problems can only be clearly recognized by solving these questions.

The mainstream at that time was still dominated by Adam Smith's classical economics and his successors' neoclassical economics. Government interference was thought to be unnecessary. However, the early twentieth century saw the emergence of a new tradition, namely, institutional economics, led by Thorstein Veblen, William Ripley, Wesley Mitchell, and others who rejected the neoclassical movement. The continuing concentration of industrial wealth and economic power and the changing nature of the modern corporate form are the rational starting points for the authors' enquiry. The concentration of economic power and dispersion of shareholdings in the largest modern companies is rapid and irreversible, which in turn facilitates the concentration of power. It also means that the market cannot effectively discipline corporations and management, contrary to the viewpoint held by conventional economists.

The core question of the impact of the separation between share ownership and control is addressed very narrowly in *The Modern Corporation and Private Property*. The impact upon the relationship between company and

employee, and between company and customers, as well as the effect on internal corporate structure, is not dealt with. Instead the authors focus on the legal aspect of corporate changes, such as the motivation mechanism and managerial unaccountability, and on the functions of the security market.

Corporate Purpose

The neglected area of the book is whose interest those in control should serve, namely, the corporate purpose. For example, if the corporate purpose is for shareholder value, then directors of the company should run the company primarily for shareholder interests. Alternatively, if the corporate purpose is for improving all stakeholder interests, then the company should not be run in a way solely for shareholder interests. Although E. Merrick Dodd (1932) questioned Berle's doctrine of corporate power in trust by asking "for whom are corporate managers trustees" before the publication of *The Modern Corporation and Private Property* in 1932, until the 1980s there was no serious academic review in this area.

It is plain to understand that the corporation used to be seen as private property, belonging to its owners, and therefore proprietors' interests should always be given priority. This conventional viewpoint of shareholder primacy received few challenges. Following the separation of ownership and control, the shareholders *de facto* surrender the power of control to managers and directors. If shareholders are no longer required to be the sole focus of the management who inherit the control, this could lead to disaster for the current and future investors.

The Modern Corporation and Private Property seems to create a little confusion with regard to the corporation's objective – that is, for whose interests it should be run. On the one hand, according to the trustee doctrine, shareholder interests are undoubtedly to be given priority, or at least not subordinated to the benefit of the corporation as a whole. On the other hand, if the corporation is seen as a social institution, as is

suggested at the end of book, then it would be expected to serve the wider interests of society as a whole.

With the development of technology, risks of externalizing costs into the wider community are increased, and therefore the importance of the corporate purpose becomes more and more vital. An obvious example is pollution emissions. If the company, or say the managers, should serve the interest of shareholders, then as long as the cost of pollution including fines and reputation loss is less than the profits brought to the shareholders, such conduct, even if it is morally unjustifiable, could be accepted according to the shareholder primacy approach. However, if we could be convinced that other groups should be taken into consideration, and that no single group's interest should be ignored, then to benefit shareholders at the expense of other groups' interests would then be unacceptable.

Nowadays, the opinion that the company should be run solely for shareholder interest attracts increasing criticism. The changing nature of private property, along with the separation of control from ownership, becomes an ideal starting point from which to reconsider the objective of the modern corporation. It also presents the possibility of the company being something of a social institution, an idea proffered by the authors at the end of the book, and whether the establishment of a "neutral technocracy" is feasible in terms of serving the broader community and balancing divergent interests.

Summary

Berle and Means's *The Modern Corporation and Private Property* is a foundational text in company law and corporate governance; many of the theoretical bases for current corporate governance structure – such as agency theory, the non-conflict rule, the insider-dealing rule, and other directors' duties – are directed, or at least largely affected, by its core theses. In other words, the "Berle-Means corporation" – a joint stock company in which ownership, in the form of numerous small shareholders, and control, in

the form of entrenched managers, are separate – is a precondition of most discussions of UK and US corporate issues.

Although some ideas in the text could be seen to draw from Veblen, Ripley, and Carver, the book presents new in-depth research and assembles all these previous notions in one volume with mathematical demonstrability. Indeed, it goes further than previous works by examining the precise nature of these changes and demonstrating that "control" could be, and indeed had been, separated from ownership of quasi-public corporations in contemporary America, rather than that such separation reflected simply the practical effect of disenfranchisement or absenteeism of shareholders. Accordingly, this collaborative work by a lawyer and an economist successfully presents a new economic epoch and brings revolutionary change to the existing economic theories.

The influence of this book is not limited to the time in which it was written. Even 80 years after its first publication, *The Modern Corporation and Private Property* is still substantially quoted by scholars expounding arguments on internal governance structure, unaccountable managerial power, and other similar issues. Besides the directors' fiduciary and non-fiduciary duties, the text created a controversy about the corporate objective, which is essential for determining the evaluation criteria of corporate governance, among other things. For business and law students, this book is still a starting point for understanding the modern corporation. In addition, the core ideas and the enduring theme of separation of ownership and control are most likely to continue to be important in future academic discussions and institutional design. At the same time, other issues raised by Berle and Means, such as the divergence of interests, corporate control transaction, and directors' accountability, continue to be principal concerns for many in the field of corporate governance.

Moral Hazard

Nirmala Lee

Guildhall School of Business & Law, London
Metropolitan University, London, UK

Synonyms

Risk; Jeopardy; Peril that is increased through morally questionable behavior

Definition and Description

Put together, the term moral hazard refers to the risk that the presence of a contract will affect the behavior of one or more parties. Information asymmetries whereby one party has more information than the other could lead to moral hazard and consequent losses for the other party. Moral hazard is the lack of incentive to guard against risk

where one is protected from its consequences such as by insurance. Indeed, a company could actually take on a higher level risk if risk insurance removes the costs of the risk from the books of the company. Pilbeam (2010, p. 497) defines moral hazard as “the problem that the existence of insurance against the event occurring will make the insured event more likely to occur than if the event was not insured against.” For example, an oil company that has insured itself against oil spills and environmental damage may act more negligently in relation to oil spills and environmental damage as it will not have to suffer the consequences of its actions.

Mitigation of Moral Hazard by Prosocial Preferences

The term “moral,” used as an adjective, dates back to the mid-fourteenth century and denotes “associated with or characterised by right behaviour”; the term is also “associated with or concerning conduct or moral principles” (good or bad), from Old French *moral* (14c.) and directly from Latin *moralis* “proper behaviour of a person in society,” literally “pertaining to manners” (Online Etymology Dictionary 2019). The term was coined by Cicero, the Roman statesman, scholar, and philosopher (“De Fato,” II.i) to translate Greek *ethikos* (ethics) from Latin *mos* “one’s disposition,” in plural, “mores, customs, manners, morals.” The term applied to indirect effect in moral support (1823), moral victory (1888), where the notion is “pertaining to or affecting the character or conduct”. Hazard (n.), c. 1300, was the name of a game at dice, from Old French *hazard* or *hasart* meaning “game of chance played with dice,” also “a throw of six in dice” (12c.), of uncertain origin. To hazard (v.) is to “put something at stake in a game of chance,” originating later in the 1520s, from Middle French *hasarder* “to play at gambling, throw dice” (15c.), from *hasard* (n.). In English, the sense of “chance of loss or harm, risk” was first recorded in the 1540s (Online Etymology Dictionary 2019).

Arnott and Stiglitz (1991) describe what they consider to be two different and competing

approaches to the problem of moral hazard: individual insurance (i.e., market insurance) and risk sharing in social groups (i.e., nonmarket insurance). Biener et al. (2018) combine market and nonmarket insurance under a group insurance scheme, which includes a contractually agreed-upon mutual sharing of losses and the assumption of joint liability to design incentive-compatible contracts when moral hazard is present. In a group scheme with joint liability, parties were found to be additionally motivated by prosocial concerns, such that the self-protection efforts become a public good that benefits all agents having joint liability. Thus, prosocial preferences that might exist between agents or the insured can be exploited by a principal or the insurer to alleviate moral hazard in a joint liability group contract. This confirms previous research that prosocial preferences might arise from the need for strategic behavior to promote cooperation in mitigating moral hazard (Casadesus-Masanell 2004; Englmaier and Leider 2012; Englmaier and Wambach 2010).

Moral Hazard and Environmental Protection

Moral hazard needs to be prevented if insurance is to enhance the sustainability of economic activities. Feichtner (2019) examines this, in the context of deep seabed diving, and agrees that, generally, insurance may enhance environmental protection, e.g., when insurers make coverage conditional on additional damage prevention measures or refuse insurance of enterprises with bad environmental track records. However, she adds the caveat that whether insurance indeed enhances the sustainability of economic activities very much depends on institutional design and safeguards to prevent moral hazard.

Research has found that firms may wish to extend insurance cover for environmental risk by resorting to increased borrowing from banks; under moral hazard, the firm may invest more by way of prevention of environmental risk than what is considered to be the optimal social level; such extended liability could lead to an increased

probability of bankruptcy for the firm as the debt component in the firm's capital structure increases and "becomes more expensive" (Dionne and Spaeter 2003, p. 1051).

Laffont (1995) points out that a large class of major environmental risks are subject to severe moral hazard problems. He examines the potential conflicts between cost minimization and safety care and considers the issue of moral hazard in environmental risk in the context of adverse selection, limited liability, risk aversion, and other factors, concluding that these contextual problems induce significant hazards for the public. Discussing the role of forest companies, Wang (2019) finds that forests are expected to play an increasing role in satisfying human needs for ecosystem services and that managing forests for the greater good is a goal, which serves as foresters' North Star on their journey toward sustainable forest management. However, on many occasions, forest companies' operations were found to give rise to negative externalities, and although governments have the power to force internalization of the externalities by levying fees or imposing regulations, these regulatory and punitive measures were found to fail frequently, due to problems of moral hazard.

Summary

Sustainability issues involve practical matters such as protecting the planet from environmental degradation and depletion of natural resources, preventing/reducing air, water, and soil pollution, and preserving the long-term health of eco systems. It is important to recognize the concept of moral hazard as highlighting the need and importance of alignment of social incentives in relation to all matters including those relating to sustainability and the environment. It is crucial that firms are incentivized to behave in a way that avoids the potential pitfalls of moral hazard and is informed by considerations of environmental sustainability.

California, Davis, CA, USA

Synonyms

[Environmental capital](#); [Natural resources](#)

Definition

Natural Capital refers to the total stock of the Earth's resources. Typical examples of natural capital include water, oxygen, minerals, and soil. Natural capital has financial value as its use drives or sustains every business operation in one way or another. From the stock of natural capital comes a flow of ecological services including processes such as waste assimilation, carbon dioxide absorption, arable land, fossil fuels consumption, erosion control, biodiversity, and temperature regulation. Natural capital may or may not be renewable and is often difficult to accurately value (United Nations Environment Programme 2012).

Introduction

Natural Capital refers to the total stock of the Earth's resources at a point in time. The available stock of natural capital can change. Some natural capital is renewable; it can be replenished (e.g., trees can be replanted). However, some natural capital is nonrenewable; it cannot be replenished or renewed at such a slow rate to effectively be nonrenewable (e.g., fossil fuels, once used, can take millions of years to renew). Thus the stock of natural capital can be depleted from the use of ecological services of nonrenewables or use of renewables at a faster than replenishable rate. Further if natural capital is degraded in some way there can be permanent depletion even if it is renewable. For example, pollution of water sources or soil erosion from climate change could cause natural capital and any natural capital associated with it to be forever lost. It is possible that the stock of renewables can be sustained, that is, its level maintained or even increased. However, at best the stock of nonrenewable natural capital can be sustained and its more normal dynamic is to be depleted over time. The rate of depletion then is a critical factor for natural capital and much effort is expended in trying to slow down the rate of depletion through technology or governmental action.

Valuing natural capital is difficult and may be truly incalculable in that without natural capital, there is no human life on the planet; thus its value may be truly infinite. While not without controversy and substantial uncertainty, valuing ecological services from natural capital may be relatively more feasible. A recent estimate placed that value at \$125 trillion per year, which is larger than current world gross domestic product (GDP) (Costanza et al. 2014). Some object to even attempting to place a monetary value on natural capital or the services it provides. As a rhetorical issue, placing monetary value on nature implies it can be consumed in the same manner as any good or service. That diminishes the true societal value of the natural capital stock and contributes to its commodification (Wackernagel and Rees 1997). Some then would prefer a physical measurement of the natural capital stock. An additional reason is that monetary values are fundamentally dependent on markets and human perception of value. For example it is possible that as the supply of one type of natural capital decreases its price will increase sufficiently such that the total monetary value remaining increases rather than decreases (Wackernagel and Rees 1997). In an aggregate measure of natural capital, this effect could make it appear that the natural capital stock has remained the same or even increased, which is misleading. While that can be controlled for, it is also still the case that those monetary values will likely not control for all of the nonmarket values that ecological services provide or the complex interactions between elements of natural capital and other aspects of human life (Costanza et al. 2014). Monetary valuation is still commonplace though as it is the most straightforward method for combining together vastly different environmental elements into one measure of natural capital or one measure of ecological services.

Current business practices involve patterns of use and development, environmental modifications, exploitation of resources, and governmental policies that support the depletion or care of the Earth's stores of natural capital. This not only has financial implications such as increased market prices due to resource depletion, but also environmental implications as the services provided by ecosystems are damaged and become less

functional (or in some cases destroyed) (Costanza et al. 1997). This use can, in turn, cause a detrimental impact to all living things, which may or may not be realized, recognized, or tracked. For example, as greenhouse gas emissions increase and areas responsible for carbon sequencing decrease, global temperatures rise, weather patterns change, sea levels increase, terrestrial and aquatic ecosystems readjust, and land and sea usability patterns change.

One of the first references of natural capital was by Schumacher (1974), described in his book *Small is Beautiful*. Work on the Biosphere 2 project brought the topic mainstream, coupled by political discourse prompted by Ralph Nader, Paul Martin Jr., and government agencies, including the Environmental Protection Agency (USA) and Natural Capital Committee, and the London Health Observatory (UK). Indicators adopted by United Nations Environment Program's World Conservation Monitoring Centre and the Organization for Economic Co-operation and Development (OECD) to measure natural biodiversity began to use the term in a more specific way. Natural capital references the natural assets in their role to provide resource inputs and environmental services for economic production, made up of three principal categories: natural resources stocks, land, and ecosystems.

Business and the Economy

As we look to industry, businesses around the globe work continuously to produce goods and services for their customers. Being sustainable in this effort refers to a firm's ability to achieve its performance goals in a way that imposes little or no harm to the environment. To be considered sustainable, when a firm uses, alters, and/or harms nature's capital, reparations, restitution, and/or restoration must be made. For those operations that genuinely care about environmental sustainability, they are accountable for their activities and use, striving to value, understand, and measure how their operations and products impact the natural environment. As human capital refers to workers, the employees of a firm's operations,

physical capital to the production implements such as buildings, machines, and tools, social capital to the communities, institutions, and society created, natural capital refers to soil, air, water, flora, fauna, and all other natural resources. These assets are all used to manufacture a wide range of goods and services, making life in the modern world possible. Our ecosystem provides resources that underpin productivity and the entire global economy. The services from natural capital flow through human capital as well as physical capital and social capital. Thus thinking about natural capital requires holistic perspective about how its value affects other capital types and their impacts on humanity's well-being. This is almost wholly absent from business decision-making (Guerry et al. 2015).

Natural capital is also a way to frame ecosystem valuation, which (in contrast to traditional economics), revolves around the idea that nonhuman life offers essential resources (e.g., oil and gas). In that sense, some view natural capital as a useful way to emphasize the need for environmental sustainability rather than an explicit need to measure and value it. Therefore, the ecological health of the planet and its sustainability is correlated with the health of the economy even though unmeasured accurately or at all. The reality is that global economy resides upon the broader economy of natural resources and the ecosystem services that sustain it. If we continue to reap the benefits of our natural environment, we must recognize the importance of natural capital within the broader economy and society writ large. Scholars concur that our ability to effectively coexist is dependent upon the conservation, reuse, and preservation of nature's capital, focusing on the valuing of quality, investing and reinvesting in the Earth's resources, as well as ensuring the proper restoration of resource depletion.

An ongoing economic issue is the extent that physical capital and natural capital is substitutable for each other as opposed to complementary with each other. From the view of classical economics, land as a proxy for natural capital is deemed separate from physical capital. The historical distinction between land and capital is that the former is naturally occurring with a fixed supply, whereas the latter refers to the implements used to produce

man-made goods and services (Wackernagel and Rees 1997). This renders physical capital and natural capital not substitutable for each other. It also gives rise to the notion that there are diminishing returns for land that, in effect, natural capital is a constraint on economic growth. It is, however, misleading to view land as if its productive capacity is fixed. Natural capital can be improved upon or degraded by the actions of human activity. Additionally, natural capital yields benefits and goods, such as timber or grain that can be harvested. Such benefits are kindred to those realized by owners of infrastructural capital, which yield more goods, such as a factory that produces automobiles (just as a maple tree produces syrup).

As economic thought evolved, it came to view physical capital and natural capital as more substitutable. Particularly it was often assumed that physical capital could be used to replace natural capital in the production of goods and services. The developments of subfields in environmental economics and ecological economics have further evolved the arguments with the former relying more on substitutability between natural capital and physical capital and the latter more on complementarity and returning to the notion of lack of substitutability between them (Wackernagel and Rees 1997). It is fair to say the dynamic between physical capital and natural capital is complex and the question about substitutability versus complementary may often be context-specific to the type of natural capital being considered.

While the general description of natural capital is not controversial, how it is valued and accounted for (e.g., aspects of ecological health, natural capital, and ecosystem services) is often contested. Various forms of accounting (e.g., cost, triple bottom line, B Corp, and other measures) may or may not include an accurate measurement of an ecological or natural deficit, along with social and financial deficits. Without a common set of agreed upon standards and measurement practices, it is difficult (if not impossible) to evaluate, value, and audit how nature impacts global performance and how firms impact the natural environment. With no common path to determine/calculate the impact to natural capital, it is

difficult to compare and contrast firms' operational influences on nature's asset bank. As ecologists work with economists to measure and express values of the wealth of ecosystems, many worry that a collapse of our planet's balanced and interdependent biodiversity will be ruined, as our ecosystem continues to be plundered by large corporations (e.g., Monsanto). The economic value of our ecosystem is rarely accounted for in manufacturing costs, and resources are simply commandeered by people, typically by the most powerful and affluent (e.g., Shell Oil). As losses accelerate and go undetected and/or are ignored by mainstream monetary analysis, authentic accountability and transparency remains absent from the picture. In effect, the spillover effects of commerce on the stock of natural capital are more often negative than positive. These effects go largely unrecorded in the unfettered marketplace. The issue can be exacerbated when standard valuation tools such as cost-benefit analysis tend to emphasize the short-term over the long-term by discounting the future in favor of the present.

Financial, Government, and Public Leadership

Financial institutions are an integral part of the economy and society. As the engine of global economic growth, the financial sector offers tools to help firms transition to sustainable development. Since virtually every economic activity can have an impact on natural capital either directly or indirectly (via the supply chain), financial institutions have considerable responsibility to the ecological footprint (United Nations Environment Programme 2012). These impacts can lead to not only material financial risks, but also to relevant business opportunities. At present, financial institutions make little or no attempts to account for and therefore value the risks and opportunities related to natural capital in their financial products and services (loans, investments, and insurance products). Building appropriate valuation and risk management tools means

taking natural capital into account within financial and investment decision-making. Stakeholders must also learn to use their voice to require the valuing and protection of natural capital, recognizing that they have a key role in demanding reforms that account for the use, maintenance, and restoration of natural capital in the global economy.

Given the Earth's resources are often deemed as a free "goods," governments must provide a framework for regulating and incentivizing all sectors of business and their stakeholders to operate responsibly regarding natural capital's sustainable use. Much natural capital can be categorized by economists either as public goods (e.g., air) or common resources (e.g., coal). In either case, they are non-excludable; that is, it is difficult to prevent others from consuming them. The issue is particularly acute for common resources where they are also rivals such that one person consuming them leaves less for everyone else. Even public goods if they become sufficiently polluted or the human population grows too large, could become rival as well. The net effect is a higher than optimal for society depletion rate, especially for common resources. This puts the natural capital stock at risk. This suggests governments need to develop clear, credible, and long-term policy frameworks that support and incentivize organizations to value and report their use of natural capital and work to internalize environmental costs. This forces private entities to explicitly consider the negative spillover effects of their actions on the natural capital stock and the ecological services that flow from it to others. The natural capital declaration commits signatory organizations to these goals with the following measures (United Nations Environment Programme 2012):

1. Requiring companies to disclose the nature of their dependence and impact on natural capital through transparent qualitative and quantitative reporting
2. Using enforceable fiscal measures to discourage business from eroding natural capital, while simultaneously offering incentives to companies that integrate, value, and account for natural capital in their business model

3. Endorsing and implementing international agreements, including, but not limited to, those agreed through the Convention on Biological Diversity and
4. Leading by example, requiring public expenditures and procurement to report and account for its use of natural capital.

Given the fact that there is no methodology in place that adequately reports and accounts for natural capital in the global financial system, business leadership is needed to undertake this concern and to elevate a sense of urgency to address this issue. Business leaders must prompt, guide, and develop interest, prompting motivated engagement and activism among their customers, suppliers, civil society, and other stakeholder groups, working to (United Nations Environment Programme 2012):

1. Cultivate increased understanding of the impacts and dependencies of natural capital relevant to firms' operations, risk profiles, customer portfolios, supply chains, and business opportunities
2. Support the development of methodologies that integrate natural capital considerations into all decision making processes
3. Build global consensus for the integration of natural capital into private sector accounting and strategic decision-making processes, while also supporting related project work that endorses natural capital coalition-building, alliances, and stakeholder group activism, and
4. Collaborate with other firms, organizations, alliances, and other stakeholders to build a global consensus around the development of a more integrated form of reporting, including natural capital as part of the wider definition of resources and relationships key to an organization's success.

A Way Forward

Environmental-economic accounting offers a conceptual framework for integrating statistics on the environment and its relationship to the economy (Winstanley and Brownlee 2014). This includes the impacts of the economy on the environment and the contribution of the environment on the economy. A coherent set of indicators and descriptive statistics can be derived that can be used to

inform a wide range of tracking, metrics that can prompt more effective policy-making activities. This includes, but is not limited to, favorable developments among the broad categories of green economy/green growth, natural resource management, and sustainable development.

The services of ecological systems and the natural capital stocks that produce them are critical to the functioning of the Earth's life-support system. They contribute to human welfare, both directly and indirectly, and therefore represent part of the total economic value of the planet. This is through both their "use value," the value entities or individuals give to the natural capital stock or ecological services that they directly use as well as their "non-use value," the value they give to the natural capital stock and ecological services even if they never use them.

Adaptive governance has been suggested as a suitable approach for ecosystem management in changing environments (Guerry et al. 2015). It rests on the assumption that landscapes and seascapes need to be understood and governed as complex social-ecological systems rather than as ecosystems alone. Scholars have compared three AG initiatives and their effects on natural capital and ecosystem services (Guerry et al. 2015). In comparison with other efforts aimed at conservation and sustainable use of natural capital, adaptive governance develops our capacity to manage multiple ecosystem services and to respond to ecosystem-wide changes. Moreover, it enables collaboration across diverse interests, sectors, and institutional operations. But the challenges to such efforts are dramatic and persistent. There are both internal and external pressures present that continuously challenge the adaptive capacity of such initiatives.

Summary

In summary, government, business, and the public must learn to have a desire to value our shared natural capital. From that point, we can work together to better understand and account for the use of natural capital and recognize its true value

in maintaining economic growth and sustaining human well-being and prosperity. If we hope to have a healthy and productive future, education is needed to foster a shift in our thinking. Caring about and accounting for the health of our planet's resources and the ecosystem that sustains life is critical toward our eventual survival.

Needs and Barriers for Local Energy Market Solutions

Samuli Honkapuro, Gonçalo Mendes, Salla Annala and Mika Luoranen
LUT University, Lappeenranta, Finland

Definitions

Distributed energy resources (DER) are “behind-the-meter” energy generation and/or storage technologies typically located at the end user premises and operated for the purpose of supplying all or a portion of the customer's electric load. The portfolio of DER technologies is wide, including electric or thermal renewable energy generation, combined heat and power (CHP) or combined cooling, heat, and power (CCHP) units, and different kinds of energy storage. The term “behind-the-meter” is meant to represent resources that are generally not connected on the bulk or wholesale electric power system, but are connected behind a customer's retail access point (the meter). These resources may be operating to serve the customer's internal electric loads or may be operating for the purpose of providing services to the bulk electric power system.

Distributed Generation (DG) refers to the portion of DER technologies that generate energy.

Microgrids are electricity distribution systems containing loads and DER, (such as distributed generators – DG, storage devices, or controllable loads) that can be operated in a controlled, coordinated way either while connected to the main power network or while islanded.

Demand response is designed to change on-site demand for energy in intervals from minutes to hours and associated timing of electric demand/energy use (i.e., lowering during peak periods) by transmitting changes in prices, load control signals, or other incentives to end users to reflect existing production and delivery costs.

Point of common coupling (PCC) of a microgrid is the single point in the electric circuit where the microgrid connects to the distribution network. Because of its internal control and coordination capabilities, the microgrid is perceived by the grid as one single electrical entity.

Static switch is a sophisticated technology device, placed at the level of the PCC, which allows maintaining high levels of PQR in particularly demanding microgrid systems, where both the power quality and the reliability of the electricity delivery are very important. Such customers can be varied, and typically of the industrial, healthcare, and services sectors.

Installed cost (of DER) is a frequently utilized cost figure in techno-economic analysis of microgrid systems whose goal is to reproduce a turnkey cost as close to real-world conditions as possible. It includes a sum of the basic and added capital costs of the generation set (which are very specific and can include several parts, such as interconnectors, exhaust sets, heat recovery, reformer, etc...), added to labor and materials, engineering, project management, and financial carrying costs during the installation period. The installed cost of DER is given as a function of the power capacity of the equipment.

Combined heat and power (CHP) or “cogeneration” is the combined generation of electricity and heat. Typically, nearly two-thirds of the energy used to generate electricity is wasted in the form of heat discharged to the atmosphere. Additional energy is wasted during the

distribution of electricity to end users. CHP is onsite electricity generation that captures the heat that would otherwise be wasted to provide useful thermal energy – such as steam or hot water – that can be used for space heating, cooling, domestic hot water and industrial processes.

Combined cooling, heat, and power (CCHP) or “trigeneration” refers to the process of simultaneous generation of electricity and useful heating and cooling using as sources the waste heat from the combustion of a fuel or the heat from solar collectors.

Primary air pollutants are pollutants directly released into the atmosphere by their generating sources. Some examples of primary pollutants are VOC, CO, SO_x, PM, and CO₂.

Secondary air pollutants are formed as a result of the interactions between primary pollutants and other elements in the atmosphere. Examples of secondary pollutants include ozone (O₃), which is formed when hydrocarbons and NO_x combine in the presence of sunlight, NO₂, which is formed through the mixture of NO with oxygen in the air, and acid rain, which is formed when SO₂ or NO_x react with water.

Description

As more energy is produced near consumption, and by customers, there is a need for a solution to trade energy locally, which is local energy market (LEM). Local energy markets provide benefits for different stakeholders. They empower prosumers' role in energy market, they promote renewable energy, and by that way climate objectives, they provide grid operators tools for procuring flexibility from demand side for congestion and balance management, and they provide new business opportunities for energy sector companies.

However, despite the benefits, there are certain barriers for implementing local energy market solutions. These barriers are typically multi-dimensional, but they can be categorized to technical, regulatory and legal, economic, and stakeholder-related barriers. Immature technology is causing high up-front costs. There exist

challenges with system integration and fault protection in microgrids. Additionally, legislative frameworks vary significantly across the EU and globally, and will affect LEM developments at a case-by-case basis. In addition to these, there might also be resistance from different stakeholders against new technology and market. These barriers are described in detail later in this entry.

Introduction

There is a paradigm shift ongoing in power systems and electricity markets. Decentralization of the power system is a trend, which is driven by a change from fossil fuels to renewables, since most of the renewable generation forms, such as wind and solar, are distributed and small-scale by nature. Hence, they are typically connected to distribution grid, as a contrary to large generation power plants, of which size are typically hundreds of megawatts and they are connected to high voltage transmission grid. In fact, solar generation is typically installed roof-top, and connected to customer-end, behind the meter. This trend is changing some of the key fundamentals of the power system and electricity markets. Power delivery, both in technological and market viewpoint, is changing from one-way delivery from centralized plant to customers, to two-direction electricity supply, where a consumer can be also a producer (which leads to a newish term prosumer, i.e., a consumer that also produces energy). As more energy is produced near consumption, and by customers, there is need for solution to trade energy locally, which is local energy market (LEM).

In addition to decentralization, renewables are also intermittent by nature, as wind and solar generation is varying based on weather. However, constant balance between supply and demand must be maintained in power system, and there are technical limits, how much generated power distribution grid can absorb, or how big loads it can serve. Hence, there is a growing need for flexibility, which typically comes in the form of demand response, or energy storages such as batteries, which both are typically in customer end.

Therefore, there is a need to trade flexibility, also locally, and empower customers to improve the flexibility of their energy use. This can be also promoted by local energy markets, and value of flexibility can be stacked by integrating local markets to open energy markets.

Needs for Local Energy Market

Local energy markets have the potential to benefit several stakeholders in the energy sector but especially the local prosumers and consumers. The benefits for different stakeholders are discussed in the following subsections.

Prosumers and Local Communities

Bid size requirements prevent prosumers from offering their generation to the centralized energy markets, but in local energy markets they can trade energy within their local community, for example, through peer to peer arrangements. Thus, local markets give consumers control over their energy affairs and allow them to be more independent (Ofgem 2017) and democratize energy supply (Koirala et al. 2016). They promote end-users' active role in the energy system by allowing them to signal their preferences, for example, for local generation and local expansion of renewables (Mengelkamp et al. 2019). Integrating different energy sectors (electricity, heating, cooling, transportation) at the local level can bring energy generation closer to consumers and reduce the complexity and inefficiency related to a purely centralized system (Koirala et al. 2016).

Local trading means that local money and profits remain within the local economy, which encourages further investments in renewable local generation (Koirala et al. 2016; Mengelkamp et al. 2018). Local energy projects encouraged by active local market may also increase local employment through employment opportunities related to building and maintaining the local generation (Koirala et al. 2016; Mengelkamp et al. 2018). Generation from local community may also be more easily accepted by the public than private or utility-based generation, as citizen engagement is a key enabler of acceptance for

energy systems (Koirala et al. 2016). Local generation can provide energy to the local community during outages of the main grid, if the local micro-grid can operate in an island mode (Mengelkamp et al. 2018).

Lower costs through self-sufficiency, lower local price level, and reduction of transmission losses are commonly mentioned as potential benefits of local energy markets (Ampatzis et al. 2014; Mengelkamp et al. 2018; Soshinskaya et al. 2014). However, although distinct price difference between local and centralized market is among the key motives for taking part in a local market, combining several different benefits/values can lead to attractive, local energy offers (Bremdal et al. 2017). Other “high value boosters” include add-on services and products, and smart capitalization on flexibility (Bremdal et al. 2017). Aggregation of local prosumers can also help meeting the minimum bid sizes in the balancing and ancillary markets and thus, local prosumers providing flexibility could receive incentives such as cheaper tariffs or direct payments for their actions (Bray et al. 2018; Koirala et al. 2016).

Furthermore, due to socioeconomic factors, such as supporting local renewable energy, local markets can be favored even if the local energy price would be higher than the external grid price (Mengelkamp et al. 2018). However, the impact of such motives may be weaker (Bremdal et al. 2017). On the other hand, the emergence of local markets and new local providers can enhance consumer choice, increase competition, and also force incumbents to improve their response to their customers’ needs (Ofgem 2017).

Society

In developed countries, local energy markets are often motivated by climate awareness, and thus carbon-neutrality in energy may be among the goals of local communities, despite the economical attractiveness of centralized systems (Koirala et al. 2016). Local markets can thus contribute to achieving the overall energy and climate objectives. Furthermore, local trading can offer a new market-based approach to promoting renewable local generation as feed-in tariffs and other subsidies are reduced (Bray et al. 2018; Ilic et al. 2012).

DSOs and TSOs

Local markets can offer a market-based solution for managing the increasingly volatile generation (e.g., solar, wind) and consumption (e.g., electric vehicles) (Ilic et al. 2012; Koirala et al. 2016). They enable network operators to introduce local price signals incentivizing flexibility for congestion management (Mengelkamp et al. 2018). Local market, where DSO procures flexibility, can be operated by the DSO or by another operator acting as an aggregator (Ampatzis et al. 2014).

Local markets can increase the renewable energy hosting capacity of distribution grids and alleviate problems related to intermittency when increasing amount of energy is consumed locally (Horta et al. 2018; Koirala et al. 2016). For example, the Cornwall Local Energy Market aims to release network capacity through intelligent management of demand, generation, and storage (Bray et al. 2018). Participants are incentivized to behave in real time according to local renewable generation. The local marketplace platform is also expected to help in coordination of distribution and transmission networks.

In addition, network losses can be reduced especially when generation and demand are matched locally during times of high energy flows (Ofgem 2017; Soshinskaya et al. 2014). In a longer term, this can help avoid network constraints and costly investments (Mengelkamp et al. 2018; Ofgem 2017).

Local markets can also help aggregate flexibility from multiple consumers, which facilitate efficient balancing of grid’s supply, and demand helps meet the minimum bid sizes in the balancing and ancillary markets (Koirala et al. 2016).

Companies in the Competitive Markets

As the energy transition is distorting the business case of incumbent energy utilities with conventional power plants, many of them have shifted their focus toward energy services and customer solutions (Koirala et al. 2016), and also new types of suppliers focusing on local benefits are entering markets (Ofgem 2017).

Managing and facilitating a local market can be handled by a smart energy service provider, which may be owned and operated by the community/

market members or by a third party (Bremdal et al. 2017). This role can also entail aggregator and retail roles and facilitating the link between the local and centralized market (Bremdal et al. 2017).

Barriers Faced by Local Energy Markets

Barriers to LEMs are abundant and multi-dimensional. Their combined effect has the potential to significantly delay the dissemination and mainstream adoption of LEMs. Due to their complex, entangled nature, these barriers have been categorized differently in different literature. In this contribution, four categories are advanced to describe “Technical”, “Regulatory and legal”, “Economic” and “Stakeholder-related” barriers.

Technical Barriers

Distributed energy resources (DER) technologies – a crucial element of LEMs – have traditionally and extensively faced barriers of a technical nature, particularly when organized into microgrids. The technical barriers faced by DER and microgrids are thus generally applicable to LEMs. Other components of LEMs, such as demand response and peer-to-peer interactions, may also encounter technical barriers.

Maturity

Most conventional DG have been widely researched and developed globally (EPA 2017; DNV 2014). Internal combustion engines and steam turbines are considered technically mature, offering a wide array of designs and complexity. Microturbines are an example of a semi-mature DER technology, whose capacity sizes and electrical efficiencies must continue to develop (EPA 2017). CO₂ emissions of microturbines are also problematic (Mendes 2017). Fuel cells for stationary applications (PAFC, MCFC, SOFC...) still face myriad technical challenges. For instance, they use hydrogen as input, which must be derived (typically) from a fossil fuel, imposing further technology and moving part additions to the system. Furthermore, while fuel cells have been marketed as a good fit for premium power

and grid-support applications, recent projects have documented low levels of reliability and availability, which call for further technology research and development (Marnay et al. 2012; EPA 2017).

The majority of renewable DER underwent major technical improvements during the last decade, today facing little to no technical barriers. For instance, the efficiency of standard crystalline silicon solar Photovoltaic (PV) modules improved from under 14% in 2005 to over 16% in 2015 (Mendes 2017). By 2019, solar manufacturers had advanced crystalline silicon panels ranging between 19% and 23% efficiency. The compactness and simplicity of PV is an asset and even operation and maintenance (O&M) problems, which were entirely human-handled a few years ago, have now been addressed via distributed monitoring and yield assurance in Information and communication technologies (ICT) platforms. On the other hand, while active solar thermal systems have been a mature and established technology since the 1970s, its multiple moving parts continue to cause problems in both residential and commercial applications. Onshore and offshore wind turbines keep increasing in size/capacity, so to be able to provide more cost-efficient energy. However, its smaller-scale applications (micro wind) have lost popularity in recent years due to various performance problems, including inappropriate blade and axis design due to the random nature of the wind in urban environments.

Systems' Integration

In some cases, the DG mix combines the production of heat or of cooling (or of both) with the production of electricity, which increases internal energy exchanges and correspondingly the technical complexity and requirements of the local energy system. For example, the exhaust heat of a gas-fueled turbine, which produces electricity, can be recovered for space heating applications. This heat can be partially used up by an absorption chiller to produce ambient cooling. This cooling needs to be transported to the end users via an energy vector (which could be water). In other cases, a fuel needs to be processed by a separate

technology before being used by the DG (ex: the need for “reforming” in fuel cell applications). Such sophisticated level of integration (more moving parts, more integrating technologies...) can impose specific types of technical barriers (depending on the employed technologies) and is usually accompanied by higher installed and O&M costs.

An additional component of integrated energy systems and microgrids is energy storage systems – ESS, whose developments and state-of-the-art have been systematically reviewed by various authors (Parra et al. 2017; Yao et al. 2016). Faisal et al. (2018) compiled major ESS issues and challenges identified in those review studies, only to conclude that the most prominent ESS barriers are system-oriented, rather than specific technology-oriented. Acknowledging that each ESS technology has its advantages and disadvantages, the study advances that new microgrid-level ESS developments should be geared toward hybrid energy storage systems (HESS), which will further enhance already existing integration and multi-operational optimization challenges. Examples are power electronics interfaces and energy management systems, which need further research and development, in order to ensure improved power quality, reliability, and efficiency of ESS operations. Safety is another issue, which calls for enhanced active system monitoring and control (e.g., of ohmic losses, temperature, etc.).

A current major trend in Europe is the promotion of Power-to-X, which may indicate that systems’ integration-related barriers will receive renewed attention in the near future.

Various microgrid projects, such as the Kythnos island and Huatacondo projects, have also reported problems with their multi-agent control, communication, and monitoring systems. These problems can influence optimal technoeconomic decisions for the system and influence the efficacy of the interactions between agents, as noted by Soshinskaya et al. (2014). Today, there is a growing variety of management and control software options. Typically, vendors offer them custom-made and using specific protocols. However, these options should be compatible with other components of microgrids so as to enable

appropriate connectivity, modularity, and efficient operations.

Grid Interconnection

The optimal interaction with the main grid enables new opportunities and value streams for LEMs, reason why it is among its key defining elements. However, there are various technical challenges linked to this interaction.

Switching from grid-connected to island mode (decoupling) – and the ability to seamlessly and quickly reconnect (recoupling) – is at the core of the microgrid concept, but represents a challenging sequence of technical steps requiring highly sophisticated voltage and frequency control, due to resulting imbalances between generation and loads (Hirsch et al. 2018; Fathima et al. 2018). Managing the instantaneous active and reactive power balances between the micro and “macro” grid is difficult under various network voltage profiles. The dual-mode operation also requires pristine DER synchronization in the presence of frequent load switching, whether in an electrical island or reconnected to the grid (Fathima et al. 2018; Hirsch et al. 2018; Hatziaargyriou 2014). This becomes more challenging if the number DER units, each with its specific power quality requirements, increases. In addition, most microgrids possess a significant share of intermittent RES generation, which may aggravate the above concern, and demand even more stringent power and frequency control requirements. Very few microgrids have been able to operate in a fully automated and grid-responsive dual-mode manner, being much more common to perform “planned islanding,” as a preventive measure to face severe weather or planned grid outages. Continued research and development of static switch technologies will be key to further unlock this type of barriers.

Electrical Fault Protection

Protection schemes and strategies against internal and external faults, which can harm system and consumer equipment (as well as operating personnel), has been a main area of microgrids’ technical research in recent years. As noted by Soshinskaya et al. (2014), while external faults could be

approached using conventional protective relaying and switching paraphernalia, overcurrent protection techniques may not be appropriate for handling internal faults in inverter-based systems. This hasn't emerged as a major shortcoming, since most microgrids operate mostly in grid-connect mode, but will likely receive more attention as the ability to island becomes more relevant.

Advanced Metering Infrastructure

The transition of the energy paradigm has digitalization as one of its enabling pillars. Correspondingly, AMI and specifically smart metering is a key component to LEM operations. Unfortunately, smart meter rollout is at different stages in various EU-countries and there is a lack of related standards and metering schemes, which means that the technical potential for more sophisticated grid/market flexibility management is not yet fully reached (Annala et al. 2018). For example, Finnish legislation (Decree 66/2009) required DSOs to implement a wide-scale smart meter rollout by the end of 2013 and currently, in Finland, close to 100% of the consumption points are equipped with a smart meter (Annala et al. 2018). This allows retailers and DSOs to offer more robust tariffs, which are inclusive of demand response incentives that better align with the system's resource efficiency (such as based on the Nordic power exchange's spot hourly price). In various countries, such as Poland, Portugal, and Belgium, smart meter implementation is still at an early stage.

Cybersecurity and Privacy

It remains unclear what technologies could be able to provide the secure and transparent environment that would be necessary for performing local energy trading. Mengelkamp et al. (2018), for example, suggests using blockchain as an enabler for high numbers of distributed continuously traced transactions. However, further research is still needed on various aspects of blockchain, such as scalability issues, complexity of the technical protocols, and actual implementation using state-of-the-art ICT components. Additionally, LEMs will incorporate the active collection and exchange of significant amounts

of different types of data, much of which is of a sensitive or confidential nature. In this context, the secure data handling and protection from various cyber security threats may become an immediate priority as an enabler of the development of LEMs. However, the technical structures, i.e., the fundamental security and privacy requirements under which these operations could take place, are not yet established (Mustafa et al. 2016), which constitutes a significant barrier.

Regulatory and Legal Barriers

The uncertainty arising from prohibitive or unclear legislative and regulatory frameworks in many countries in Europe and around the world draws concerns over the future development of LEMs, as well as of DER and microgrids.

Legal Obstacles and Uncertainty

Country-specific legislation inherited from the legacy energy paradigm can be particularly prohibitive of microgrid architectures that incorporate multiple DER. As noted by Ali et al. (2017), in spite of growing interest in DG, there aren't as of yet in Europe clear policies, standards, or regulatory instruments geared toward the repercussions of DG integration into electric power systems.

RES penetration regulation is a major bottleneck. For example, in Spain, the RD 1699/2011 prevents the combination, in the same metered electrical circuit, of PV generation and loads, as well as the behind-the-meter deployment of ESS together with PV. Other regulations prevent promotion of RES generally, as well as different tariff innovations. (Sanz et al. 2014) Taxation issues also persist. For instance, in Finland, owners of electric storage assets are taxed on both the electricity used for charging and the discharged electricity – double taxation (TEM 2017). Such legislative frameworks vary significantly across the EU and globally, which poses further normalization challenges.

Some barriers are related to the absent legal definition of key concepts such as LEMs, or "microgrids." This delays progress, due to lack of standardization both at the technical and policy levels. To the best of knowledge, only in the US

legal microgrid definitions have been introduced, namely, in the state law of New York, New Jersey, California, Connecticut, and few others. Furthermore, in Europe, directives from the Clean Energy package opened the precedent for regulating the concept of “citizens energy communities” with the ability to autonomously manage several energy initiatives of their own, which is now being transposed by many member states (for instance, Greece and Finland). However, practice from regulation is yet to be seen and numerous inconsistencies still exist that will create legal uncertainty (RESCoop 2018).

Community energy systems also require distribution infrastructure, which will inevitably cross privately or publicly owned land (Wouters 2015). This will raise legal issues and conflicts of interest, especially in cases where the network intersects local distribution network rights-of-way, which DSOs hold under long-term franchises and pay for, typically at the city level.

Lastly, DER ownership is difficult to define legally, for which further regulatory clarifications are generally required (Valta et al. 2018). In the USA, public utilities from various deregulated market states, such as Pennsylvania, Maryland, and Illinois, have approached regulators in order to be able to own microgrid assets, which has so far been declined. Another rather contentious point has been the microgrid asset cost recovery model, which has been often extended to the entire utility’s customer base, rather than limited to the communities directly involved with the project (Wood 2018).

Grid Interconnection and Trading Rules

Grid interconnection policies have been historically geared toward managing impacts from increasing DER penetration. This fits a paradigm that perceives DER as sources of grid disturbances (Soshinskaya et al. 2014). Contrarily, LEMs contemplate DER as sources of active cooperation with the grid and as enablers of new revenue streams and business models with the ability to enhance the local economy.

In many countries of Europe, such as Portugal, Spain, and widely in the USA, anti-islanding regulations establishing disproportionate grid

protection schemes still threaten the development of microgrids. Such schemes prevent the seamless decoupling and self-sufficient operations that are innate to microgrids (Wouters 2015; Soshinskaya et al. 2014). From a grid perspective, taking in variable and unpredictable DER capacity requires infrastructure and equipment upgrades, which not always operators are willing or able to sustain. As a result, it remains unclear which parties should be financially responsible for these added costs (Ali et al. 2017). The uncertainty in interconnection policies will continue to drive long and fastidious administrative procedures and delays in getting project approvals and permissions (Valta et al. 2018) – a risk that will inevitably keep potential investors away.

A second branch of obstructive grid connection regulation pertains to bi-directionality. A fundamental ability of LEMs and microgrids is not only to buy but also to trade energy and power within different marketplaces and with a multitude of customers. However, the prevailing market frameworks are either inadequate or entirely impeditive of such activities, barring these systems from potentially key revenue streams. Globally, various countries still prohibit feeding self-generated electricity into the grid (REN21 2019). In Europe, many states, including Denmark, Greece, and Switzerland, rolled out net metering or similar schemes. However, in many cases, such as Spain and Portugal, these regulations are fully geared toward self-consumption, thus discouraging sales of surplus production and other types of active market participation (Government of Portugal 2014; Sanz et al. 2014). Behind this context are institutionalized trading rules that remain unclear as to who should acquire surplus production from DER. Additionally, well-structured compensation mechanisms to regulate the participation of prosumers in flexibility or ancillary markets are largely unavailable. For example, the economic regulation of the DSOs often incentivizes infrastructure investments over the use of demand response (Vallés et al. 2016). Mechanisms for valuation of externalities, such as added reliability and curbed environmental emissions, are equally unavailable, which further aggravates the value proposition for LEMs.

Another side aspect of this discussion is the reallocation of distribution grid O&M costs, which DSOs usually recover via electricity tariffs. It is unlikely that DSOs will get on board with prosumer export trends before clear distribution cost recovery mechanisms – for instance, via capacity-based charges in sales revenues – are established.

New Actors and Redefinition of Roles

The decentralized energy paradigm from which the LEMs concept was born involves myriad structural transformations, including the redefinition and creation of certain market activities and roles. This is unavoidable in innovative environments and constitutes more an opportunity, particularly for new third-party players or prosumers to enter the energy market than a barrier of substantial importance. For example, a new breed of competitive players is likely to emerge with the technical skills and capacity to operate, maintain, and manage local energy systems such as microgrids, as well as to validate and securely coordinate intrinsic LEM transactions. On the other hand, at least in the USA, various public utilities have filed requests with local utility commissions to be able to own and operate DER assets themselves, by which they would further delve into competitive market environments (Wood 2017). This balance of powers, through which the new decentralized energy market frameworks are taking shape, is still underway, and can be considered itself the real barrier to more swift market developments. Meanwhile, a significant new area of research in LEMs pursues the development of novel business models that drive the creation of financial value for its intervening actors, such as prosumers engaged in local peer-to-peer trading, or in demand response and ancillary service markets.

Economic Barriers

Some challenges faced by LEMs have an economic nature and affect different types of stakeholders.

Installed Costs

Local energy projects still bear high upfront costs, which affect their financial performance (Ali et al.

2017; Mendes 2017; Koirala et al. 2016) and their attractiveness to investors. This is mostly (but not exclusively) a result from high installed costs of less market-mature DER, such as microturbines and fuel cells. Capital costs for the latter, for example, are currently aggravated by the need for a reformer system, as addressed earlier. The techno-economic maturity of DER is often discussed in the literature (EPA 2017; Parra et al. 2017; Yao et al. 2016; DNV 2014). Essentially, solar PV reached such levels of maturity through the last decade (approx. 70% installed cost reduction) that its cost-efficiency against the BAU has been enabled in most scenarios. Stationary energy storage solutions are generally still lagging behind in terms of techno-economics, even though cost reductions are soon expected for technologies such as Li-ion or flow batteries (Faisal et al. 2018). The integration of energy systems may also pose financial challenges to LEMs. System capital and O&M costs increase proportionally with the number of energy conversions involved (for example, hot or chilled water distribution networks may become necessary). DER management systems – DERMS, which centralize control and coordination of the various assets, as well as interconnection equipment at the grid point of common coupling (PCC), such as static switches, can also increase costs substantially.

Distribution of Value

Other economic barriers to LEMs have a socio-economic dimension and are generally tied to inappropriate or absent regulation. For example, split-incentive problems, as reported by Koirala et al. (2016), can occur in local energy system developments if investment costs and reaped benefits are not equitably balanced among project stakeholders, i.e., investors and beneficiaries. This is particularly aggravated by the lack of asset ownership and revenue generation models suitable to this type of projects. To avoid split-incentives, it is critical that stakeholder interests are properly mapped and a fair distribution of value is assured already at a pre-project stage (Koirala et al. 2016). Various authors address, as well, the customer impacts of grid defection (Valta et al. 2018; Winkler and Ragawitz 2016).

Electricity prices may increase (including for non-prosumer customers) as a DSO response to higher self-consumption shares. Faced with decreasing revenue from grid fees, the DSO, on the other hand, may see its ability to invest in grid development and maintenance financially compromised. Grid defection also disrupts the traditional public electricity service tax collection model in place in many countries (Faure et al. 2017). Even though much research has been done in this area (Hanna et al. 2017; Mendes 2017) and some utilities are experimenting (LADWP 2019), no established prosumer tariffs exist that successfully balance local generation benefits with traditional electric rate cost components, thus avoiding cross-subsidization between customers (Valta et al. 2018).

Stakeholder-Related Barriers

This group of barriers says respect to the sensitive interactions between the involved market actors.

Customer Engagement

Effective customer engagement is a vital step for the development of functional LEMs (Soshinskaya et al. 2014). Local and community energy project developers can face resistance from customers lacking concrete project details or understanding of the technologically innovative concepts at play, or simply unwilling or unable to engage (Lopes et al. 2016). This type of resistance to change may become more acute and sensitive to handle when projects take place in socially fragile areas. There are complex socioeconomic layers behind this behavior, reason why it is critical that such projects adopt sophisticated social innovation techniques that are fully inclusive and embracing of the cultural diversity and richness of their customer base (Klein et al. 2019). Another difficulty lies in the intangible nature of many LEM benefits, such as the lowering of global impact emissions (such as GHG emissions) and the promotion of local growth, which are not easily perceived by the majority of customers. Generally, customers identify more easily with benefits immediately perceived as attainable or quantifiable (Timmerman 2017).

Privacy and Value Sharing

The direct control of customer loads can raise not only privacy issues, but also conflicts of interest. In a centralized control scenario, customer energy flexibility can be commercially leveraged by a variety of actors, for example, in the balancing power market, ancillary services market, or simply to maximize local generation. Due to this, it becomes crucial that proper value sharing models are set and that clear rights and obligations applicable to balance responsible parties are established.

Market Pressures

Under most current regulatory and market frameworks, grid-connected local energy systems under the “good citizen” policy, i.e., those perceived by the network as one-directional consumer loads rather than as prosumers, are generally preferred (Soshinskaya et al. 2014). Distribution companies will naturally exert pressure against prosumer exports until, as previously discussed, clear electricity buy-back regulations and proper service models that incorporate their network upgrade requirements are in place. Likewise, self-consumption and local trading take market revenue away from traditional energy suppliers and reduce customer contribution to covering grid O&M costs. Concerns with loss of market share and positioning are likely to drive further resistance from traditional market actors (such as larger generator and operator companies), even though renewed opportunities to provide new types of services are expected to emerge for these players, as a result from their legacy market position, experience, and skills.

Environment Impacts

Local energy system projects are generally seen as environmentally positive. However, concerns have been raised as to the potential local air pollution impacts of a scenario where distributed energy adoption becomes mainstream, particularly in urban pockets (Mancarella and Chicco 2010; Strachan and Farrell 2006). While renewable energy-based DER do not incite such a concern, fossil-fueled DG, such as CHP or CCHP microturbine or engine units, have emission levels

that justify further research (Mendes 2017). It is often assumed that distributed energy emission impacts are limited to CO₂. However, this is not the case. Burning fuels for local generation raises the local concentration of primary pollutants such as NO_x, SO_x, VOC, CO, or CH₄, which are, in many cases, already high in urban areas, due to human activities such as transportation. Chemical reactions involving these pollutants and a series of climatic factors (such as sunlight) give rise to secondary air pollutants, such as ground ozone and particulate matter, which have many adverse human health effects, typically linked to cardiac and respiratory diseases, among others. A deeper consideration of these phenomena may result in stringent siting regulations with potential to further delay the implementation of LEM projects.

Summary

Local energy markets have the potential to benefit several stakeholders in the energy sector, especially the local prosumers and consumers, as they promote end users' active role in the energy system. Benefits for society are related to climate objectives, as local energy market solutions promote renewable energy. Furthermore, grid operators benefit from the increased local flexibility, which can be used for maintaining the power balance and for congestion management. In addition to these, novel market solutions provide new business opportunities for aggregators and other service providers.

However, despite the benefits, there are certain barriers for implementing local energy market solutions. These barriers can be categorized as technical, regulatory and legal, economic, and stakeholder-related to barriers. Nevertheless, these barriers are typically multidimensional.

NEET Youngsters

► NEET Youngsters Management

NEET Youngsters Management

Silvia Puiu

Faculty of Economics and Business
Administration, University of Craiova,
Craiova, Romania

Synonyms

Employment or training; Management of NEETs;
NEET youngsters; NEETs; Not in education

Definition

NEET Youngsters Management is not a science derived from management. It is about using principles of management at various levels (micro or macro, public, or private level) in order to solve the problem of NEETs (not in education, employment, or training) that are usually youngsters between 15 and 34 years old (Eurostat 2019). The problem with NEET youngsters is that they are invisible and becoming older; thus, they are not included in these statistics, because they will be more than 34 years old. So, NEET youngsters become adults, and sometimes there are families formed by NEETs, thus increasing the risk for having children that will also become NEETs. According to OECD (2018), the analysis on NEETs refers to youngsters between 15 and 29 years old that are not in education, employment, or training. The International Labour Organization (www.ilo.org/global/about-the-ilo/multimedia/maps-and-charts/enhanced/WCMS_598674/lang%2D%2Den/index.htm) appreciates that NEETs refer to youngsters between 15 and 24 years old and that this indicator is widely influenced by gender and location. Eurofound

(2018) mentions that the age group of NEETs was previously 15 to 24 years old, being later extended to 15 to 29 years old. The origin of the term can be found in a report of Social Exclusion Unit (1999) when the term was first used in order to change the previous term that was considered as not being inclusive and fair to youngsters (status zero). At first, the acronym included only youngsters between 16 and 18 years old. Since then, the term has been extensively used in global statistics from Europe, the United States, South Korea, and Japan, each country adding its specific. There is also an indicator, NEET rate, determined as the share of the youngsters in a specific age group not in education, employment, or training in the total number of youngsters in that age group.

Introduction

There are differences in the NEETs' situation in Europe, the United States, Japan, or South Korea. As in the UK case where there was the term "status zero" that was changed with a more neutral one (an acronym for an objective reality), in Japan there are also two terms: freeters and NEETs. The terms used in Japan might seem similar, but the difference is that freeters have a part-time, temporary job, while NEETs do not have one. The other features (the age group of 15 to 34 years old and not being in education) are the same (Inui 2005). So-youn (2015) analyzed the causes for the high number of NEETs in South Korea. If in some countries, one of the causes for becoming a NEET youngster is represented by not having an education, the author highlights that "eight out of ten South Koreans graduate from a university," this making youngsters "pickier" when having to find a job. Schmid (2013, p. 1) also mentions that the number of NEETs in Korea is one of the highest in OECD countries, "especially for youth with tertiary education." DeSilver (2015) analyzed the situation of US NEETs between 16 and 29 years old and concluded that there are more NEETs among black and Hispanic people and those who have only high school education or even less. Another report of Pew Research Center (2019) shows that there are less NEETs in the

United States as "economy recovers." The report presents the NEET figures between 2013 and 2018 for the age group 16 to 29 years old. These differences in age group make statistics regarding NEETs in the world more difficult to compare.

Risk Factors for Becoming NEET

In order to properly manage the problem of NEET youngsters, it is important to know the term, the differences between countries, and the main causes and risk factors that determine a youngster to become NEET. Among the main risk factors, we can mention the following: the lack of education or over-qualification correlated with the difficulty to find a job for that qualification, the low income of the family, the region where youngsters live (rural areas or poor regions), and gender (women are more prone to becoming NEET because of early pregnancy). The latest report of Eurostat (2019) regarding the number of NEETs in EU countries reveals the risk factors. The analysis by sex and age shows that there are more NEET women between 20 and 34 years old than men, some of the causes being "social pressures" (women are expected to stay home and take care of the household), "gender segregation," and discrimination from potential employers. The analysis by the educational status reveals that those with low-level education are more prone to becoming NEETs than those with intermediate- or high-level education. There can appear some situations in which youngsters overqualified prefer to not work if they do not find a job appropriate to their level of education. The analysis by the geographic position shows that youngsters in rural areas face a higher risk of becoming NEETs than those in urban area.

Depending on the causes that make a person staying under this category of NEETs, we can have various forms of NEETs: voluntary or involuntary if the youngsters have or do not have control of this status (sometimes, they do not want to work or continue education but prefer to write, travel, or express their artistic side); elite NEETs (youngsters in rich families that decide not to work); shut-in or the Japanese term hikikomori

(Uchida and Norasakkunkit 2015) when youngsters remain inside their houses, becoming socially isolated (without a medical reason, at least not physical); and short-, medium-, or long-term NEETs, depending on the time of being under this category.

Disadvantages of Having a High Number of NEETs and Their Potential for a Country's Development

The NEET status has numerous disadvantages and long-term risks for those youngsters: their economic and social status will be affected, their income will dramatically decrease, their health will also suffer, their psychological health will deteriorate, and they will face a lack of hope and perspective and have difficulties to start a family. These disadvantages gain higher proportions at a national level because NEETs are an important human capital with a great potential for the development of the country. Each NEET youngster is an unused human resource and costs the economy money and productivity. Integrating NEETs will bring many advantages for macroeconomic indicators and lead to a more developed country.

NEET Youngsters Management

The problem of NEETs can be managed at different levels: individual, national, or even global. The NEET individual can learn to apply some life strategies that could help him or her get rid of this label. OECD (2016) considers NEETs "disengaged youth." So, how can a disengaged youngster be transformed into a motivated one, eager to continue his or her studies or find a job? The answer is that it is very difficult for someone being NEET to awaken himself or herself without the help of government or NGOs. At a national level, there should be more investments in education, thus preventing school abandonment and diminishing the risks for becoming NEET. Other measures that can be implemented at a national level are offering after-school programs for disadvantaged youngsters (minorities, children from

rural areas, or children from families with low income, with parents who left abroad to work); combining formal education with nonformal education and creating partnerships with NGOs to adjust the educational activities to the needs of NEETs or those in risk of becoming NEET; creating special programs for the integration of NEETs in the labor market and offering them an incentive to enroll in the programs; monitoring youngsters with a risk of becoming NEETs; monitoring NEETs to prevent them being invisible in the society; offering temporary support (financial or nonfinancial); offering career counseling in order to help youngsters choose a career after they graduate; creating partnerships with private companies in order to offer internships to students, thus preventing the NEET phenomenon and also to NEETs; and using Youth Guarantee schemes (since 2013, EU member states had to implement them). Investments in education are a key to the NEET problem. At a global level, the United Nations adopted the 2030 Agenda for Sustainable Development establishing 17 sustainable development goals (www.un.org/sustainable-development/sustainable-development-goals/). From these goals, at least two can be related with the problem of NEETs or the risk factors for becoming one: goal 4, quality education, and goal 8, decent work and economic growth.

NEETs are a concern for all of us and represent a mirror for how a community knows how to tackle this problem. Each of us can contribute in our own way to the achievement of the goals in the 2030 Agenda.

Summary

The term NEET should be reconsidered. NEETs should not be seen as a burden but as a potential that is not yet well valorized in the society. The country that succeeds to do that better and faster than other countries has much to gain. And a question that should stick with us in order to motivate us to do more for these youngsters at a national or global level is: *What happens with NEETs after the maximum age that classifies someone as being NEET (34 years old)?*

Net Neutrality

Milan Todorovic

Guildhall School of Business and Law, London
Metropolitan University, London, UK

Synonyms

Non-discriminatory Access [also Non-discriminatory Broadband/Bandwidth and/or Traffic Management]; Open Internet

Definition

An uncomplicated definition of the term is *Equal treatment of all online data and content traffic*. Still, a careful reader may recognize the considerable complexity of the matter at hand.

A “reductionist” approach may place Net [work] Neutrality within the technical contexts of “inter-network” access through constituent physical means of reaching the internet and its many digital media/software components. At first glance, it is an obscure intersection of law and technology.

Initially, the question defining the matter is: Should internet service providers (ISPs) supply equal (quality and speed of) access to legal content of all types, methods of delivery, and

application(s) to all users of the internet and if so, under what classes of circumstances?

However, thus defined right of equal access to legal content online captures a number of other important fundamentals of the internet and its constituent media. These specify the context and impact of many if not all aspects of internet communications. Such terms include relative positions of power of major players, users, consumers, and citizens online; internet economics; the nature, reach, scope, scale, and impact of internet marketing; business models; free competition; fostering or obstructing innovation; and, moreover, the weighty concepts of public interest, freedom of speech, fake news, human rights, democracy, government dependability, and corporate social responsibility (e.g., FCC.; Free Press, [n.d.](#); Vesteinsson, [2019](#)).

Introduction

The specific use of the term can be traced back to a 2003 paper (Wu, [2003](#)), though matters known as Net Neutrality and Open Internet have characterized information and communications technology (ICT)-driven networks since the late 1990s. Specifically, those notions arose during the early commercialization of the internet¹ (Reardon, [2015](#)).

The term Net Neutrality, thus worded, was initially specific to the USA and its regulators and unique market structures. The 2003 paper, articulating key “network neutrality” principles, subsequently influenced US policy the Federal Communications Commission’s (FCC) policies on vertical integration of broadband, ISPs, and content suppliers (FCC, [2013](#), pp. 5691–4).

Largely interchangeable with Net Neutrality is the notion of Open Internet Regulation, as it is known in corresponding documents (e.g., EU/EEA). Despite varying views and terminologies, Net Neutrality remains a term in broad global use and appears in many known international and national debates. Those favoring free-market

deregulation argue that EU/EEA open internet rules considerably impair the pace of innovation compared to the USA (Swanson, [2015](#)).

As commercial broadband emerged, Wu ([2003](#)) presented a case for ISP self-regulation rather than rigorous legislation, which he considered counterproductive. Instead, official bodies would impose light-touch regulation of all broadband suppliers, espousing the need for non-discrimination of access to legal content and latency-sensitive applications. (The latter includes existing software transmitting voice or video via the “*inter-network* of networks.”)

Technology arguments of the day were soon surpassed, and Net Neutrality debates moved to new ground. This, especially as the vertical integration of those controlling content and access, had occurred on a large scale soon after the paper made its considerable impact. Nonetheless, the survey/fieldwork cited in Wu’s seminal paper does cite a less neutral approach on the part of cable firms, i.e., content suppliers, which soon became vertically integrated within broadband markets.

The Open Internet/Net Neutrality faced its greatest test to date with the adoption of new FCC rules in December 2017, actioned in 2018 (Kaye et al., [2018](#)). Some, especially advocacy groups, denounced this as the end of Net Neutrality and internet freedoms as such (McSherry, [2017](#)).

The debate remains an impassioned one.

Complexities, Activism, Litigation, and Implications

The most basic way of defining Net Neutrality relates to equal right of access to legal content through established networks, with specific focus on tech firms, ISPs, and ICT networks in disseminating legal content and applications. However, the technical core of Net Neutrality obscures more complex and nuanced assertions, which may be classed under political economy, power relations, open culture, and rights of groups and individuals in media and communications.

¹ (An important VoIP/Voice over Internet Protocol test case helped define “non-discrimination” in 2005.)

Historically and to date, terms of Net Neutrality and Open Internet primarily relate to the “physical” networks owned and/or controlled by service suppliers. Technology aspects of Net Neutrality are undeniably important. However, this may disguise matters of competition, regulation, legislation, and, especially, freedom of expression. The matter is stridently upheld by liberal/leftist proponents of free speech and sustainable development on one and free-market advocates on the other side.

Thus, opposing concepts of “free” are espoused: While the notions of openness, collaboration, and curbs on corporate power prevail on the “liberal/left,” their critics label such thought naïve, lacking in rigor, and idealistic/ideological in nature while asserting in favor of market-oriented competition (Campbell, 2017). Considered views acknowledge nuances and complexities, citing concerns over the convergence of content provision and technical delivery which may lead to the significant marginalization of economically disadvantaged, individualist, or minority views in [online] media. Implicitly, it is reasoned this may amount to distortion and suppression of information.

Advantages of low cost and free basic access include benefitting the hard-up, as stated or pondered by major decision-makers (Finley, 2017; Kaye et al., 2018). The UN rapporteur on the rights of freedom of opinion and expression reflected that state actors may owe the ultimate remit of facilitating open internet access (Kaye et al., 2018; Miles, 2017). Involving ICT corporations where required – as means of access develop over time – he emphasized that universal access to quality information is the key criterion.² Other expert opinions firmly advocate the benefits of free-market approaches; further decrying COVID-triggered reformist calls to make internet a public utility (Swanson, 2015, 2020).

Themes debated further (e.g., Harris & McCabe, 2017) extend toward the function and privacy of user data; commercializing the labor of

internet users both paid and unpaid; stretching to the very notion of human cognition; and how it may change under the pressure of market forces that disseminate information, facilitate processing, and enable content access.

The Net Neutrality argument had triggered considerable policy and political deductions in the late 2010s, embodied in a number of high-profile regulatory contexts within respective legislatures of the USA and EU (e.g., BEREC, 2016). These repeatedly raised key matters concerning democracy, market competition, and the rule of law. Such themes are reflected in decisions involving at times the highest legal instances (Keating & Davidson, 2019; Liptak, 2018).

Tracing the issue back to its 1990s origins shows that technology acts as substructure, thus merely shaping the means that lead to more significant ends. Despite constant technological change, the crux of the argument had shifted little since the time of dial-up connections when the notion of the *Internet as public utility* first reappeared in the public eye. (Failing to invoke The Communications Act of 1934 [US].) Early internet service providers appeared on the market in the 1990s; by the end of the decade, they requested access to fiber-optic cables already in use for cable television in the USA.

Thereby internet-related corporate interests had first clashed vis-à-vis the network itself: tackling the contrasting *physicality* of a dated [copper-]wire telephone network technology used for dial-up connections and a far superior cable infrastructure offered by entertainment services. The latter indeed were able to offer broadband due to sunk costs of investment into their existing TV infrastructure network. Thus, early ISP-focused businesses argued being at a disadvantage.

The attempt to treat the broadband network as a public utility similar to that of the telephone service had failed on such occasions³ (Roosevelt Institute, 2011). What can be derived from such

²On the other hand, at the peak of COVID-19 crisis, an unprecedented alliance of Apple and Google was reported, not without critique in privacy groups.

³As stated, there are opinions being voiced which suggest that the COVID-19 pandemic may change that, as nearly the entire world moved into lockdown, adopting remote working, and social life (Livni, 2020).

examples is that regardless of technology, the access to – and use of networks, information, data, content, and applications – is a matter both preceding and surpassing a given technological context.

From the mid-to-late 2010s, and especially since 2017, the Net Neutrality debate had once more become a heated one. As the technology had improved significantly and the vertical integration created new giants capable of investing in *new and novel* infrastructures, so has the argument moved to more sophisticated aspects of network usage and purpose.

Potential Future Developments

Policy, Innovation, and Global Leadership

Since its inception, internet [and related regulation] in America led the way: In terms of networks, businesses, diverse applications, platforms, and innovation. Many national (Ofcom, 2019) and supranational (BEREC, 2016) treaties and regulations including those concerning the Open Internet in democracies and other (supra)state actors tend to follow, reflect, or at times contest some of its features. The world largely conforms with developments determined by the internet in the USA. In that light, Net Neutrality matters debated in the USA continue to reverberate worldwide.⁴

The Science and Technology Aspects

“Physicality” is a term best determined by traditional scientific definitions: those of Physics. Namely, that both tangible and intangible methods are physical in nature, allowing for interchangeable use wherever possible or required: The tangible nature of internet wiring is as physical as the wireless methods of data transmission. The latter are yet to fully develop and are inherently constrained by the limitations of Earth’s electromagnetic spectrum despite the fact that digital compression allows for data packets of greater efficiency. Though this is the

case, future data connections and networks are likely to move to a more *intangible physicality* with new imperatives, technologies, and policies emerging to serve them.⁵

The internet of the future is also likely to evolve further into a hybrid medium, a blend of intangible – *electronic and data* – physicality and its tangible emanations such as the actual, perceptible tangibility of IoT (Internet of Things, smart homes, and 3D/4D printing). Therefore, the full span of possibilities would extend beyond present information/data/entertainment networks and create ones that cover matters ranging from those as abstract as *new storage media for ideas (human cognitive processes thus far unprotected in material form)* to matters as concrete as roboticization of everyday life. This would lead to exceptionally complex power relations, ethical and legal considerations, and such like.

Summary

Net Neutrality is a hotly debated matter that is hard to pin down by means of a single definition. The seminal paper that articulated the notion of “Net Neutrality” at the outset of these debates dealt with a technological issue now long surpassed; however, the notion remains challenging despite, and indeed because of, constantly evolving technologies that support the internet and its numerous facets. To simplify without circumventing the matter at the heart of it: Net Neutrality is equally about technology as it is about the ownership of it; it is about the control and ownership of networks and device- and software-centered patents as much as it is about the principles of human rights, freedom of speech and expression, and freedom from control or censorship all at once. It is also about the balance of power between the individual, the state, and the supranational bodies – corporate and regulatory

⁴For example, the EU’s BEREC Guidelines appear to contrast the US regulation unfolding since 2016.

⁵A separate matter surpassing this entry is “how ‘green’ is the internet”: the more latency-driven data exchange is, the *less green* it may be; streaming and blockchain are some of the better-known examples of the internet’s innate sustainability flaws.

alike – just as it is about elaborate and drawn-out legal definitions that tend to evolve with and in cases preceding technological change that facilitates or prevents freedoms of access or dissemination. It remains about market competition as much as it is intrinsically political. It is both discursive and pragmatic in nature. It is not without irony that some of the loudest advocates of its abolishment are reportedly affected by the very notion of empowering the tech that supports it.

²Department of Agricultural and Environmental Engineering, University of Ibadan, Ibadan, Oyo state, Nigeria

Synonyms

Carbon neutrality; Climate neutrality; Decarbonization; Net zero carbon footprint; Net zero greenhouse gas (GHG) emission

Definition

Net zero emission is a concept which is similar in theory to that of climate neutrality. The concept was borne out of the need to avert the worst climate impact. It refers to the system of reaching a net zero emission of carbon dioxide (CO₂), methane, and other greenhouse gases in the atmosphere by removing all man-made greenhouse gas emissions from the atmosphere through reduction measures (natural and artificial sink), making-up for emission with removal of carbon from the atmosphere (carbon-offsetting) or by simply not emitting to reach net zero. This is possible where public and private concerns as well as individuals

act to remove as much CO₂ as they put into the atmosphere. The goal here is to reach overall carbon neutrality which leads to a zero-carbon footprint (IPCC 2018; Oshiro et al. 2018). For example, an industrial entity may embark on an afforestation program and funding other projects for an equivalent amount of carbon saving in a different location in the world to compensate for its greenhouse gases emission. There are also a growing number of energy efficient buildings that generate their energy needs on and/or off-site from renewable sources. Net zero emission hypothetically describes a solution where the amount of CO₂ and other GHGs emitted into the atmosphere is equal to the amount removed (IPCC 2018).

$$\text{CO}_2 \text{ emitted} = \text{CO}_2 \text{ removed}$$

Net zero emission is also sometimes used interchangeably with carbon neutrality and net zero carbon footprint which both refer to achieving net zero emissions by balancing carbon emissions including other greenhouse gases (GHGs) measured in terms of their carbon dioxide equivalence. The term “zero emission” is the root phrase from which “net zero emission” is derived. Even though the two terms are ultimately geared toward addressing the goal of balancing the global climate, they are conceptually different (Hope and Kuhn 2018). Zero emission was first conceptualized in 1991 by Gunter Pauli when he found that the growing demand for the derivatives and by-products of palm oil has aggravated the destruction of the rainforest in the South-East Asia. Overall, net zero emission refers to technologies, processes, and other energy generating facilities which do not emit greenhouse gases or other waste that can deteriorate the quality of the environment. Thus, common zero emission technologies include zero emission mobility such as bicycles, electric cars, hydrogen cars, and electric trains. There is also zero emission power generation such as hydroelectricity, solar power, wind power, and nuclear power. In order to reach the global warming target in the Paris Agreement, global emissions should reach net zero around mid-century (Friends of the Earth 2018).

Introduction

The use of energy has been a major driver of economic and social development. This has enabled the human race to lead some form of comfortable and enjoyable life. The growth in technological development is a result of the abundance and use of fossil fuels; that indeed fostered the era of industrial revolution. Nonetheless, the widespread consumption of fossil fuels has led to the release of excess greenhouse gases (GHGs) and other toxic elements into the environment (Eyre and Killip 2019). These GHGs are capable of trapping more heat in the atmosphere with a consequential negative impact on the climate, such as global temperature rise. This occurrence is known as climate change. The higher the production of GHGs, the higher the degree of earth warming, increasing the incidence of such adverse impacts as bushfires, storms, heatwaves, flood, etc. Cumulative emission of anthropogenic CO₂ has been identified as the major contributor to postindustrial anthropogenic temperature increase (Friends of the Earth 2018).

Globally, the demand for energy is projected to increase significantly over this century. However, to stabilize the global mean temperature, the net emissions of carbon dioxide (CO₂) from human activities – including not only energy and industrial production, but also land use and agriculture – must approach zero (Abraham 2019). The necessity to limit the emission of CO₂ and other GHGs has become more pressing than ever as reliance on fossil fuels to meet the growing global demand for energy continues. While the energy demand in industrialized countries will remain high to sustain their development, demand is growing fast in countries in transition due to their growing population and an increasing standard of living (Glynn et al. 2019; Abraham 2019). It is imperative to address associated ecological and climate issues. In its report of 2018, the IPCC has shown that the net global carbon emission must be reduced to zero to reverse the trend in warming of the earth. The report stressed that any scenario that does not entail the global reduction of emission to zero is

not capable of addressing the challenge of a changing climate. Figure 1 depicts the sectoral distribution of CO₂ emission on a global scale. It has been projected that the increase of global average temperature beyond 2 °C from pre-industrial level will cause tropical regions like West Africa, South-East Asia, Central and northern South America to face substantial decrease in local yields, particularly for wheat and maize. A mean temperature of 2 °C would also cause sea level rise by 10 cm, relative to 1.5 °C and a 30% higher rate of increase by 2100 (Roberts 2018; Davis et al. 2018).

In an agreement reached by 196 countries in Paris, a target was set to hold the global average temperature increase well below 2 °C above pre-industrial levels and also to strive to limit the temperature increase to 1.5 °C above preindustrial levels. Meeting the Paris Agreement goals will require reaching net-zero CO₂ emissions globally by 2050 through the provision of policies to address climate change and high carbon development (Eyre and Killip 2019).

Achieving Net Zero Emission

Reaching net zero emission by 2050 requires actions in adopting low carbon emission pathways that enhance the widespread deployment of clean energy sources to replace fossil fuels, as well as the reduction of total energy demand through higher energy efficiency and changes in consumer behavior. Massive production of carbon-neutral and energy-dense liquid fuels may be critical towards the provision of energy that is needed to drive the stationary and transportation energy production sectors, such fuels include hydrogen and ammonia, biofuels, synthetic hydrocarbons, and direct solar fuels (Glynn et al. 2019).

To achieve the goal of net zero emission, there has to be a shift in policy orientation at all levels, technological development must be tailored to international climate goals, and corporate and individual behavior has to change to protect the environment (Levin and Davis 2019). However, net zero emission can be achieved mainly in three ways:

Net Zero Emission, Fig. 1 Global fossil fuels and industrial emissions, 2014. (Source: Davis et al. 2018)

- (I) Emission offsetting: this refers to the reduction or avoidance of emission of CO₂ or other GHGs in one sector to compensate for emission made somewhere else. This can be achieved by investment in energy efficiency, renewable energy or other low-emission technology. The emission trading system (ETS) of the European Union is a good example of emission offsetting system. Emission offsets are measured in tons of carbon dioxide equivalent (CO₂e). Emission offsetting operates in two markets levels. In the higher compliance market, governments, companies, and other entities can purchase emission offsets to enable them to comply with their emission limits. In the lower voluntary compliance market, governments, companies, and individuals can buy emission offsets to compensate for their emission from transportation, electricity, and other emission contributions (Revkin 2007).
- (II) Carbon removal/sequestration: this refers to the removal and long-term storage of atmospheric CO₂ to mitigate the effect of global warming. Carbon sequestration occurs both naturally and through artificial processes (Selin 2020). CO₂ is removed from the atmosphere naturally through biological, chemical, and physical processes and stored primarily in green plants and trees, in soils as organic debris, in geologic formations that are inactive for indefinite period, and the oceans. This is the process with which nature has achieved balance in atmospheric CO₂ in a way that optimally supports life. However, several artificial processes have been developed to achieve similar purpose such as large-scale artificial sequestration of industrially CO₂ emissions through subsurface saline aquifers, reservoirs, or direct air capture (Sedjo and Sohngen 2012). It has been projected that through improved land-

use practices, about 600 mega-tons of CO₂ equivalent (MtCO₂e) per year of GHG can be captured and removed from the atmosphere, which amounts to about 10% of 1990 emissions (Selin 2020).

- (III) Emission reduction: this refers to the minimization of the amount of CO₂ and other GHGs emissions through adjusting industrial, agricultural, and other processes, for example, the use of renewable energy sources (e.g., solar and wind energy) and energy efficient processes to reduce emissions. Though both fossil fuel and non-fossil fuel-based energy sources produce emissions, nonfossil fuel-based energy sources produce significantly low emissions (Sedjo and Sohngen 2012).

Challenges

The major factors hindering the attainment of net zero emission include the high capital of the existing technologies, poor energy efficiencies, and people's attitude to the use of energy. To therefore achieve the full decarbonization of the environment, there is a need to enhance technological cost reductions via research and innovation. Other factors, among other, are:

- (a) Most carbon neutral fuels have a considerably lower gravimetric and volumetric energy densities than the conventional fossil fuels: this implies that most carbon neutral or synthetic fuels such as hydrogen fuel and biofuels cannot store as much energy per unit volume or mass as the conventional fossil fuels. Thus, while they are likely to be more expensive, most synthetic fuels produced from renewable sources have lower energy content than fossil fuels (Pearson et al. 2012). Therefore, carbon neutral fuels have limited utilization efficiency and their suitability is dependent on the energy demands of an infrastructure or a journey.
- (b) Stiff competition between food security and bioenergy production: though the development of bioenergy has received tremendous

acceptance globally in the quest for greener environment, the rate of bioenergy development has also begun to brew concerns for its nexus with food security. This is because most of the food crops such as cassava, soybean, groundnut, and sugarcane among other energy-rich crop which form the basic food crops especially in most countries also constitute feedstocks for biofuel production (Matemilola et al. 2019).

- (c) Lack of policies that target long-term systemic changes in the energy sector: energy consumption across the industrial, transport, residential, and commercial sectors are responsible for the greater share of global emissions. Emission of GHG imposes costs on society; thus, an emission pricing system could be an important tool in the bid to decarbonize the energy sector. However, carbon pricing policies have so far seemed very difficult to enact and implement in many developed and developing countries. Certification and performance measurement policies are other essential tools for decarbonization but implementation in the energy sector have been torrid (Zogopoulos 2019).
- (d) Large scale deforestation and ineffective land use: deforestation accounts for about 15% of global carbon emissions, making it a key driver of climate change. The need to eliminate deforestation can therefore not be over-emphasized. In their pursuit of carbon neutrality at the Bonn climate summit, 2017, 27 countries including Brazil and Indonesia committed to increase the use of wood products for energy generation with the plan to plant new saplings that could reabsorb the CO₂ emitted by fully grown burned trees within years to decades. Scholars have however argued that this effort will create huge demand for wood and increase deforestation that could pose unimageable grave threat to the world's carbon sink (Neslen 2018).

Summary

To avert a dangerous level of global warming, it has become inevitable to reverse the global GHG

emission trend and ensure it reaches net zero by mid-century. Though energy is the primary driver of economic growth, most of the global emissions arise from energy use. It is therefore imperative that the global energy system is decarbonized. In the light of the growing global emission pattern, world leaders agreed in Paris, to pursue efforts to keep the global average temperature increase well below 2 °C above preindustrial levels and to further strive to limit the temperature increase to 1.5 °C above pre-industrial levels. To reach this target, governments, corporate organizations, and individuals have a key role to play. Key approach to achieve net zero emission include removal of carbon from the atmosphere via afforestation/ reforestation, enhanced mineral weathering, or direct capture of CO₂ from the air. Emission trading as well as emission reduction through energy efficiency and use of renewable energy sources represent some of the core approaches.

New Generation of Academics Programme

Sinikiwe Mzezewa

Department of Commercial Law, University of Cape Town, Cape Town, South Africa

Synonyms

[nGAP; Staffing South Africa University Framework \(SSUF\)](#)

Definition

The New Generation of Academics Programme is a policy by South Africa's Department of Higher Education to address staffing ratios, funding for new academics and institutional transformation. The program also focusses on mentoring of new academics. The Department of Higher Education requires annual progress reports to monitor the implementation of the program.

Introduction

The Staffing South Africa University Framework (SSUF) established the New Generation of Academics Programme (nGAP). The framework was a response to the challenges in universities in the size, composition, and the capacity of academic staff (Department of Higher Education and Training of South Africa [2015](#)). The challenges faced by South African universities are mainly attributed to the colonial and apartheid-era policies. The policies also filtered into institutions of higher learning, and the impact thereof continues to be a conundrum for policymakers. Race and ethnicity shaped South African universities (Weber and Vandeyar [2004](#)). In addition to race and ethnicity, the staff mainly consisted of white males (Badat [2010](#)). During the colonial era, English universities (University of Cape Town, University of Witwatersrand, University of Rhodes, University of Pretoria, and University of Natal) were

established to cater for white population, and the faculties consisted of members from Britain and European countries. After the establishment of the University of Cape Town, Stellenbosch University was established and catered for Afrikaans white persons. During the apartheid era, the government established four Afrikaans universities, and they excluded blacks. English universities admitted very few blacks. Legislation in the 1950s allowed for the creation of exclusive black universities (Weber and Vandeyar 2004). According to Heleta (2016), exclusive black universities were established to train black people to serve the colony and later the apartheid state. In 1983 the apartheid government enacted a policy to allow admission of black students into white institutions. The policies also transcended to the funding of the universities, and adequate funding was provided to white institutions, while the black universities were underfunded and located in impoverished rural areas (Jansen 2003).

South African Universities Post-democracy

Given the history of South Africa, it is evident that the universities had to undergo an institutional transformation. Fourie (1999) defined institutional transformation as a broader societal transition, which refers to the changes in the political, social-economic, and cultural-educational structures of society. Transition in higher education refers to the significant structural conversion of a national system of higher education that takes place over an extended period. Further mentioned that transformation of South African Higher Education takes place on different levels, namely, organizational culture and acceptance of new culture. In 1995 the Ministry of Higher Education embarked on efforts to transform universities (Fourie 1999).

It appears that the government efforts soon after democracy were not sufficient to achieve the transformation goals. Weber and Vandeyar (2004) conducted a qualitative research that showed there was a lack of transformation and

elitism, thus leading to the academics assimilating conservative pedagogical practices from their white colleagues. They concluded that historically, white universities were a site of struggle for change in critical areas such as black representation, institutionalized racism, university governance, and the curriculum. Badat (2010) in a report commissioned by the Development Bank of Southern Africa recommended a new generation of academics that is increasingly constituted by blacks and female South Africans who are suitably qualified. Badat further argued that while the employment of “suitably qualified” black women must be improvised, it might also lead to exclusion of other highly qualified Africans from other countries (Badat 2010). Another incident that showed that policy implementation is not always sufficient was the highly publicized incident at the University of Free State. Suransky and van der Merwe (2016) described the incident as the “Reitz Incident” where white male Afrikaner students recruited five black middle-aged cleaners to reenact humiliating initiation activities and throughout the video sarcastic references were made about the university transformation activities.

Staffing South Africa University Framework

Given research that had been conducted post-democracy and the outcry of lack of transformation, there was a need to implement programs to address the concerns. Therefore, a framework was established which seeks to address transformation and staff-student ratios, enhancing the qualifications and effectiveness of existing staff. The SSAUF showed that in 2012, the overall academic workforce remained predominantly white, making up to 53.2%. In terms of gender, the report showed that women constitute 44.6% and are underrepresented in senior academic ranks constituting 29.5%. The best student-staff ratios are represented in the previously advantaged universities. Also showed that just over one-third of the academic staff in permanent positions held a doctorate because a doctorate was recognized as a

necessary but not sufficient factor to improve the overall quality of educational processes in South Africa (Department of Higher Education and Training of South Africa 2015).

The framework envisaged allocating posts for 6 years by recruiting highly capable scholars as new academics. The program covers 6 years for each cohort, which is a 3-year development program and 3-year induction. Further, the cohorts are assigned a mentor, and the universities are required to provide annual reports to the Department of Higher Education (Department of Higher Education and Training of South Africa 2015). Universities have responded positively to the nGAP program; several candidates were appointed as nGAP scholars.

To further support the new academics, the National Research Foundation (NRF) established a research grant for nGAP scholars. The NRF of South Africa was established in terms of the National Research Foundation Act 23 of 1998. The Act provides that the foundation was established to promote research and transfer of knowledge. The funds of the foundation consist of money appropriated by parliament, income accumulated by the fund, donations, contributions, etc. nGAP research fund was established to provide research grants to young academics in the first and second year of appointment from 2016 and a maximum of 250 academics in a year. The objectives of the nGAP research grant are to accelerate doctoral-level training (Funding Instrument: DST-NRF Research Development Grants for New Generation of Academics Programme (nGAP) Scholars 2019).

There are mixed reviews on whether the goals of transformation are being achieved. Fomunyan (2017) argued that the current state of South African Higher Education is a debatable one and is characterized by discordant values and a variety of opinions. Further, the former white universities claim that they are working toward transformation student, whereas there is little evidence to support the claim (Fomunyan 2017). The long-term feasibility of the program is yet to be assessed because the program is still operational.

Summary

This entry gives a general understanding of a policy by South Africa's Department of Higher Education, New Generation of Academics Programme. The policy is a response to problems of higher education which were inherited by the democratic government. The policy aims to address staffing ratios, funding for new academics and institutional transformation.

New Markets

Oluwasegun Seriki
Technological University Dublin, Dublin, Ireland

Synonyms

[Business expansion](#); [Innovation](#); [New business frontiers](#)

Definition

Anderson and Gatignon (2008) espoused that new markets do not emerge nor do they appear but are created via deliberate activities of firms. The creation of these new markets can be either on purpose or by accident, and this usually occurs when firms sense a need in the market and communicate their solution to fill that need.

New markets are created as a consequence of firms seeking to become more competitive and develop their markets, and this can be achieved either via the introduction of new products/processes or when economic factors shift resources to a new market segment/location that support a firm's innovative solutions.

In essence, new markets do not simply appear but are created as a result of either intraorganizational or extraorganizational processes such as institutional entrepreneurship or internationalization (Davis et al. 2008). New markets also emerge via a culture of innovation and changes in contemporary society (Weber et al.

2008). Thompson and MacMillan (2010) posit that visionary businesses play a critical role in creating new business models that open up new markets. Some companies do so by introducing new innovation-driven products, targeted at increasing buyers' utility (Bresnahan and Gordon 1996), while others create new markets by leveraging existing products (Anderson and Gatignon 2008).

Defining new markets is an interesting as well as challenging task, and this chapter will explore critical issues within the definition of new markets such as business expansion, innovation, culture, and knowledge transfer incentives for exploring new markets among other matters.

New Markets: Why Create Them

The creation of new markets is due to varied reasons: market development, innovation, need to diversify current offerings, emerging technologies, and among other reasons. The need to explore new markets may be due to various reasons within firms such as the convergence of ICT, turbulence in retail channels caused by the internet, new product development, the increasing concentration/interdependence of industries, and globalization (Roberts 2000). Some theorists within the Schumpeterian school of thought opine that the entrepreneur delivers new markets, i.e., most new markets are supply-driven (Metcalf 2004). Other authors posit that new markets can be created by developing submarkets in rapidly developing economies or industries such as customers in emerging markets (Thompson and MacMillan 2010). Another means of creating new markets, known as the “supply-push approach,” highlight that these markets are consumer-driven and are created in areas where there are no more guesses about what might appeal to consumers (Geroski 2002).

New markets are also created due to saturated domestic markets, firms seeking to expand/grow their business, or to gain economies of scale (Seelos and Mair 2005). Organizational politics and the pursuit of private firm subgoals may also be responsible for the search for new markets or

the desire to spread risks over different market segments (Anderson and Gatignon 2008).

These market creation activities do not come without their unique challenges, which are detailed in the next section.

Challenges to New Market Creation

Lord and Ranft (2011) posit that when firms move outside their home or current markets, several obstacles to success within these markets present themselves. These challenges were called “liabilities of foreignness” by Zaheer (1995), some of which include barriers to effective decision-making (caused by high levels of uncertainty), local governments and partners bottlenecks, and the numerous challenges of customizing processes/products to different cultural and national requirements.

Seelos and Mair (2005) also espouse that economics or logistics challenges are key issues that present barriers to new market creation, particularly in developing or third world countries. Other problems may include securing markets for radically new technologies or securing early profit footholds in rapidly growing social, economic, or demographic change (MacMillan and van Putten 2008).

How can firms creating or moving into new markets mitigate risks and overcome these barriers? Four suggestions for overcoming obstacles in new markets are outlined:

- Having a set of deliberate experimentation processes in place that will lead to the design and development of an emergent business model with limited exposure
- First exporting to overseas buyers before setting up fully in the country
- Using an agent, setting up local distributorship or joint venture agreements
- Partial set up to “test the waters” before moving to full production

The risks mitigation factors outlined above are nonprescriptive but only provide a guide for firms or individuals looking to provide goods or services in new markets.

Summary

This chapter explored the critical issues in the creation of new markets, particularly what a new market is, and the characteristics of new markets and barriers to their creation. The reasons why firms choose to venture into new markets and the possible problems that they might face are discussed, in addition to risk-mitigating strategies. Overall, the concept of new markets is for the development of new growth stimuli, measures and business expansion models. Firms can explore new markets not only for gaining business advantage but also for reputation and maximizing the loyalty of their existing client base.

Nicholas Capaldi

Samuel O. Idowu
Accounting, London Metropolitan University,
London, UK

Basic Biographical Information

Professor Capaldi received his B.A. from the University of Pennsylvania and his Ph.D. from Columbia University. His principal research and teaching interest is in public policy and its intersection with political science, philosophy, law, religion, and economics. He is the author of 10 books, over 100 articles, and editor of 7 anthologies. He is a member of the editorial board of ten journals and has served most recently as editor of *Public Affairs Quarterly*.

Professor Capaldi is the recipient of grants from the National Endowment for the Humanities, The Mellon Foundation, The U.S. Department of Education, The Board of Regents of Louisiana, and the John Templeton Foundation among others. He is an internationally recognized scholar and a domestic public policy specialist on such issues as higher education, bio-ethics, business ethics, affirmative action, and immigration.

Nicholas Capaldi is Legendre-Soulé Distinguished Chair in Business Ethics at Loyola University, New Orleans, Louisiana, USA. He is the founder, Chief Executive Office, and President of the Global Corporate Governance Institute (GCGI) a research network of CSR, Sustainability, Ethics, and Governance from around the globe. He also serves as the Director of the Center for Spiritual Capital. He taught previously at the University of Tulsa where he was McFarlin Research Professor of Law; Columbia University; Queens College, City University of New York; The United States Military Academy at West Point; and the National University of Singapore.

Intellectual Portrait

Nicholas Capaldi's fundamental interest has always been on the meaning and sources of morality (moral philosophy). When he entered the discipline of philosophy, the reigning doctrine was the positivist view that there was no rational basis for morality and that David Hume's distinction between "is" and "ought" was the definitive proof of that position. Capaldi's dissertation, as well as in numerous later published articles and books (*Hume's Place in Moral Philosophy*), established that this was a serious misrepresentation of Hume. Hume's position was just the opposite. He, along with Donald Livingston, revolutionized Hume scholarship.

When it once again became fashionable (1970s) to employ philosophy in the service of morality (as well as politics, economics, etc.), a newer and later version of positivist thought known as analytic philosophy employed a form of normative discourse (he called it *exploration* as seen in the prominent works of Rawls, Nozick,

and Dworkin) that led, Capaldi argued, not only to the collapse of all civility in debate/discussion and an end to rational discussion, but also served primarily to aid hidden political agendas and the total politicization of civilization. Capaldi then became a leading critic of analytic philosophy (*The Enlightenment Project in the Analytic Conversation*), an opponent of politicized social science, and a prominent spokesperson for pluralism in the American Philosophical Association. His textbook *The Art of Deception* introduced an innovative method for helping students to engage in critical and self-critical thinking.

In an attempt to provide an alternative understanding of normative issues, Capaldi turned to the works of Wittgenstein, Hayek, and Oakeshott. He developed the concept that norms were the product of the ongoing explication of cultural inheritances, hence the inevitability of moral pluralism. In this context, theologies and philosophies were often no more than the veiled advocacy and rationalizations for premeditated positions with private agendas. Subsequently, he articulated his own cultural inheritance, its history, development (see his award winning book *John Stuart Mill* published by Cambridge University Press), its inner tensions, and its capacity to deal with or manage internal and external conflicts. His most recent three books (*America's Spiritual Capital*; *Liberty vs. Equality in Political Economy*), all coauthored, are examples of this approach (see most recently *The Anglo-American Conception of the Rule of Law*).

Capaldi approached business ethics from this same perspective. He began by criticizing the dominant paradigms in the research done on business ethics and corporate social responsibility ("Theory and Method in Business Ethics"). He was the first to elaborate a comprehensive account of the norms of modernity as reflected in Anglo-American culture ("Ethical Foundations of Free-Market Societies"): the Technological Project (TP for short, the transformation of nature for human benefit), that the TP was best carried out in a pro-growth market economy, how such an economy required limited government, how limited government required the rule of law, and the latter existed most clearly in a culture that

promoted individual autonomy. He also identified the tensions and conflicts within that paradigm. He continues to address the commercial norms most consistent with that paradigm. He has also established the *Center for Spiritual Capital* at Loyola University New Orleans to study the relation between those norms and a Catholic religious commitment. He has specifically highlighted the different perspectives of Pope John Paul II and Pope Francis.

Major Contributions

Professor Nicholas Capaldi, an Ivy-educated philosopher, has distinguished himself as an academic writer, editor, and researcher. In a career spanning six decades, he has produced 10 books, 7 anthologies, 3 textbooks, and over 80 academic journal articles. The excellence and prominence of his contributions to the world of academia stands clearly for all scholars regardless of their fields to see. For example, Professor Capaldi's 2004 book – *John Stuart Mills*, published by Cambridge University Press – has been a subject of *laudatory* reviews in prestigious outlets like the *Washington Post* and the *New York Review of Books* as well as extended Television treatment on C-SPAN's BookNotes.

Capaldi has provided an unrivalled and distinguished service to academic journals, for example, as the Editor of the highly regarded *Public Affairs Quarterly*. With all these outstanding achievements in academia, it became apparent why Capaldi earned tenure, earned promotion to full professorship, and currently occupies the *second* endowed chair of his highly productive career.

Capaldi has been referred to by his colleagues and those who know him as the *rare* academic business ethicist who can speak compellingly the language of business in the classroom because he has spoken it where it counts – on the trading floor, in the market with real money at stake because Professor Capaldi worked on Wall Street at Bache Securities (since absorbed by Prudential Financial) in their trading department. Conversationally and directly, he gains almost

immediate credibility with his students – a rare gift which only few business professors (whether or not business ethicists) can boast. Marcoux (2006) comments “there may be bigger names in business ethics, but there is none more credible than Nicholas Capaldi.”

Publications in business ethics are as follows:

Nondiscrimination

Benedetta Siboni¹ and Jellie Molino²

¹Department of Management, Alma Mater Studiorum Università di Bologna, Forlì Campus, Italy

²University of Turin, Turin, Italy

Synonyms

[Antidiscrimination](#)

Definition

Broadly speaking, nondiscrimination requires that all people should be treated in the same way (or equally), based on the generally accepted principle that all human beings are equal in dignity and rights (UN 1948). Hence, discrimination occurs when people are treated differently in a way that impacts negatively on their human dignity (Ackermann 2006) or for arbitrary reasons lying on individual features, such as race and ethnicity, skin color, sex, sexual orientation, religious belief, class, etc.

However, several legislations worldwide distinguish between formal and substantial equity, which justifies differential treatment to ensure substantial equity among citizens. The primordial objective is to remove political, economic, and social obstacles that limit the development of person and his/her political, economic, and social participation. Indeed, positive discrimination (also called affirmative actions) may be justified in cases, for example, of advancing differential treatments toward underrepresented groups to compensate for past discrimination. Such actions do not represent discriminations if they do not establish separate rights for different groups and are not continued after achieving their goals. Nondiscrimination, therefore, intersects both with equality in opportunity (i.e., everyone competes under equal conditions based on his/her capabilities) and equality of achievement (i.e., equality in results) (Deskoska 2010).

Moreover, nondiscrimination relates to the novel term “intersectionality,” indicating that multiple forms of discrimination (such as racism, sexism, and classism) often overlap. Instead of considering any discriminatory act as a distinct and isolated case, it should be analyzed in a whole, particularly on how it intertwines in the experience of the people involved.

Introduction

Several forms of discrimination have been in practice for a long time worldwide, such as those based on race or ethnicity, sex, sexual orientation,

religious belief, disability, family status and class, age, name, culture, language, etc., and some still exist.

Discrimination can either be direct or indirect: the former implies treating different groups in a different manner, involving less favorable treatment; the latter (also called disguised discrimination) is represented by an apparently neutral disposition or behavior that puts people holding specific characteristics or belonging to a certain group at a particular disadvantage compared to others.

Some prominent past direct discriminations were regulated by laws and denied certain groups the right to ownership over themselves or other rights. It is the case of slavery and slave trade; racial segregation policies such as apartheid; the discrimination against Gypsies, Slavs, etc.; and the anti-Jewish laws enacted during the Fascist and Nazist regimes. Moreover, transversal to the whole world and historical periods, some laws prohibit voting and property rights for women and discriminate for sexual orientation (homophobia) and divergent political opinions. Some of these discriminations have ceased, albeit recently. For example, despite slavery mostly ended at the end of the nineteenth century, the formal end of slavery in Ethiopia is dated only in 1942 (Bonacci and Meckelburg 2017), while South Africa established apartheid in 1948 which ended only in 1994 (Pons-Vignon and Anseeuw 2009).

Despite modern democratic societies have surpassed most cases of discriminations by formally adopting the principle of equality of rights to all people, with specific features allowing some positive discrimination to guarantee substantial equality (e.g., Galizzi and Siboni 2016), discriminations still exist in some countries, mostly in less developed ones.

Most Muslim countries still maintain a formal and informal severe form of discrimination toward people belonging to religious minorities (especially toward Christians), which sometimes results in persecutions (Bandow 2020). In India, although the caste system was officially abolished in 1950, it still has a strong impact not only on the general balance of power among various groups

of the society but also on specific cases such job distribution, transactional activities on mere transfer of goods, and the act of choosing who to marry (e.g., Mosse 2018).

In many Arabic countries, women do not have the same right as men, and they must have a male guardian and are often under his power (usually the father or the brother and, after the marriage, the husband). In some cases, their right to vote is still restricted (e.g., Saudi Arabia), or they do not have access to education after 12 years old nor are allowed to ordinary activities such as playing sports or even choosing their dress (e.g., Afghanistan). They cannot work even if they are widows, nor leave the house without being accompanied by a man, except in a few limited cases, under penalty of punishment (Albrecht et al. 2022; Nehan 2022). Several countries criminalize homosexuality (Human Dignity Trust 2022), and in some parts of Africa and Asia, it is still punishable by death penalty (in most cases the punishment concerns only male homosexuality).

Even in modern developed democracies, despite women voting and participating in public and political life since the mid-1900s, informal discrimination at the workplace still exists due to several factors, such as widespread male chauvinism and the tasks of social reproduction. This discrimination reduces the female employment rate; hinders their career progression, especially in qualified occupations; and causes a higher gender pay gap (e.g., Bishu and Alkadry 2017; EC 2021, 2019). This is an example of indirect discrimination: what appears to have general application to all (e.g., equal employment opportunities to women and men) sometimes results to indirect discrimination (i.e., gender pay gap) or to a situation arising from a practice, rule, requirement, or condition that is neutral on its face but hits disproportionately at particular groups (Lord Lester of Herne Hill 1992) or has different influence on different groups (Deskoska 2010).

Another recent example of indirect discrimination is the equal access of all to the modern technology on genetic information for purpose of determining early detection and prevention of possible genetic disorder that has resulted to indirect discrimination against people with genetic

predisposition: people lost not only their jobs but also some health insurance including economic well-being due to unfair use of genetic information (e.g., an increased chance a person will develop a certain disease based on his/her genetic makeup). As a consequence, in 2008, the Genetic Information Nondiscrimination Act was approved in the United States, to prevent indirect discrimination against people with genetic predisposition. Accordingly, it is forbidden to employers for requiring genetic information from their employees and applicants (Ackermann 2006).

Additional examples of indirect discrimination occur in case tax where foreign persons or objects are taxed unfavorably, by imposing higher taxation against imported products from certain countries resulting in negative economic effects on competitors from other countries (Diebold 2011). To address this type of discrimination, international tax treaties such as the 1977 OECD Model Double Taxation Convention on Income and Capital have provisions prohibiting differential tax treatments resulting in possible double taxation (van Raad 1981). In fact, international economic treaties such as the World Trade Organization General Agreement on Tariff and Trade have already enjoined countries from treating domestic market actors more favorably than foreign market actors (known as “national treatment”) or providing different treatments to foreign market actors from different origins (known as “most favored nation treatment”) (Diebold 2011; De Boynes et al. 2009).

Instances of Declarations and Conventions Against Discrimination

International regulatory frameworks establish the nondiscrimination principle. Most of them are based on the United Nations (UN) Universal Declaration of Human Rights (UN 1948). It states that all people are born free and equal in dignity and rights. Hence, the Declaration bans any kind of distinctions related to individual features, such as race, color, sex, language, religion, political or other opinion, national or social origin, property, birth, or other status. Furthermore, the Declaration

prohibits distinctions on the basis of the political, jurisdictional, or international status of the country or territory to which a person belongs.

The Declaration was born to address racial discrimination perpetrated by Nazi Germany. According to the Declaration, the dignity and the equal and inalienable rights of all people worldwide are the bases of freedom, justice, and peace. It was proclaimed as a common standard that the UN member states adopt to promote universal respect for human rights and fundamental freedoms. Moreover, it adopts progressive measures, national and international, to secure their universal and effective recognition and observance, both among the peoples of the states themselves and among the territories under their jurisdiction.

Notably, the Declaration states the right of anyone to be equal before the law and the right to equal treatment before the tribunals and includes the fundamental right to have recourse to legal means against any discriminatory behavior.

On the bases of this Declaration, the UN promoted a series of conventions:

1. The Convention against discrimination in education (UNESCO 1960) adopted by the UN Educational, Scientific and Cultural Organization entered into force in 1962. The Convention addresses both formal discriminations stated by laws and not deliberated discrimination derived, for instance, from administrative practices and social, geographical, economic, and historical circumstances. Such discrimination affects some minority groups that do not have access to quality education. The Convention obliges states parties to adopt a national policy to promote equal treatment in education.
2. The International Convention on the Elimination of All Forms of Racial Discrimination (UN 1965) entered into force in 1969. It requires states parties to engage in a policy aimed at avoiding and contrasting any discrimination based on race and punish any discriminatory behavior based on race, color, or ethnicity. The Convention defines racial discrimination as “any distinction, exclusion, restriction or preference based on race, colour,

descent, or national or ethnic origin which has the purpose or effect of nullifying or impairing the recognition, enjoyment or exercise, on an equal footing, of human rights and fundamental freedoms in the political, economic, social, cultural or any other field of public life” (art. 1, par. 1). Further, the Convention lists several political, civil, economic, social, and cultural rights that must be guaranteed regardless of racial differences. It also provides for affirmative actions as special measures to ensure adequate advancement of certain racial or ethnic groups or individuals requiring such protection to equal enjoyment or exercise of human rights and fundamental freedoms.

3. The International Covenant on Civil and Political Rights (UN 1966) entered into force in 1976. It recognizes that the effective enjoyment of human rights, as stated in the Universal Declaration, is achievable only under the realization of everyone’s civil and political rights, as well as economic, social, and cultural rights. In particular, the Covenant affirms the right of self-determination of all peoples to freely choose their political status and pursue their own economic, social, and cultural development. The states parties undertake to promote the realization of the right to self-determination and respect it, without distinction. Moreover, it states the individual, having duties to other individuals and to the community to which he belongs, is under a responsibility to strive for the promotion and observance of the rights recognized by the Covenant.

The Covenant follows by listing, among others, the prohibition of torture and inhuman or degrading treatment or punishment, the prohibition of slavery and any form of compulsory and forced labor, prohibiting arbitrary arrest or detention, the right to be equal before the courts and tribunals, the right of defense and due process and presumption of innocence, and the right to hold an opinion and freely express it.

Notably, as stated by the UN Human Rights Committee in the General Comment No. 18 of the former Convention, entitled to

Nondiscrimination (UN HRC 1989), it obliges states parties to develop nondiscriminatory laws and regulatory frameworks concerning equity and equal protection, conceived at basic principle relating to the protection of human rights. Laws must be enacted to entitle all persons to equality and equal protection, prohibit any discrimination, and guarantee equal protection against discrimination. In addition, states must ensure equal rights between men and women. Further, promoting national, racial, or religious hatred that constitutes incitement to discrimination should be banned. Specifications are made regarding spouses' equal rights and responsibilities as to marriage, during the marriage, and at its dissolution.

Moreover, the Committee suggests widening the definition of discrimination, including any distinction, exclusion, restriction, or preference based on features "such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status, and which has the purpose or effect of nullifying or impairing the recognition, enjoyment or exercise by all persons, on an equal footing, of all rights and freedoms" (par. 7).

Notably, the enjoyment of rights and freedoms on an equal footing may involve non-identical treatments. For example, in countries which have not abolished the death penalty, the Convention prevents people under 18 from being sentenced to death. Also, the Committee stresses the role of affirmative actions as a legitimate differentiation to diminish or eliminate the conditions that cause or contribute to perpetuating discrimination. However, treatment differentiations do not constitute discrimination if the criteria on which they are based on are reasonable and objective and aimed at achieving a legitimate purpose under the Covenant.

4. The Convention on the Elimination of All Forms of Discrimination Against Women (UN 1979), entered into force in 1981, defines discrimination against women as: "any distinction, exclusion or restriction made on the basis

of sex which has the effect or purpose of impairing or nullifying the recognition, enjoyment or exercise by women, irrespective of their marital status, on a basis of equality of men and women, of human rights and fundamental freedoms in the political, economic, social, cultural, civil or any other field" (art. 1).

It recognizes that extensive discrimination against women continues to exist and violates the principles of equality of rights and respect for human dignity. Discrimination against women hinders the participation of women in the political, social, economic, and cultural life of their countries on an equal footing with their male counterparts. Furthermore, it makes it more difficult for women to fully develop their potential, which is reflected in that of their countries and humanity because men and women cannot contribute to it in a free and equal way. The Convention is rooted in the fact that, usually, women have less access to food, health, education, training, employment opportunities, and the satisfaction of other needs in situations of poverty. Hence, discrimination against women hinders the growth of the well-being of society and the family. In this regard, the Convention emphasizes that the role of women in procreation should not be a basis for discrimination but that the education of children requires a sharing of responsibility between men and women and society as a whole. Therefore, a change in the role of men and women in society and the family is required to achieve full equality between men and women.

Accordingly, states parties of this Convention are required to adopt all appropriate means for the practical elimination of discrimination against women by person, organization, or enterprise, including all appropriate measures aimed at modifying the patterns of social and cultural behavior of men and women to eliminate prejudices, customs, and all practices based on the idea of inferiority or superiority or stereotyped roles for men and women.

Also, states parties must adopt measures to ensure the full development and advancement of women in all fields, in particular in the

political, social, economic, and cultural areas. In doing so, the adoption of temporary special measures (i.e., affirmative actions) is mentioned.

Specific dispositions have been made to ensure no discrimination against women and their public and political life participation as well as on the equality of rights and obligations of spouses, the free choice of marriage, and the choice of the spouse and concerning children.

5. The Convention on the Rights of Persons with Disabilities and Its Optional Protocol (UN 2006), which entered into force in 2008, raises consideration for people with disabilities from being mere “objects” of charity, medical care, and social protection to “individuals” with rights and capable of making life decisions based on their free and informed consent, as well as being active members of the society. Indeed, according to art. 1, the Convention’s wish is “(. . .) to promote, protect and ensure the full and equal enjoyment of all human rights and fundamental freedoms by all persons with disabilities and promote respect for their inherent dignity.”

Furthermore, it requires removing the obstacles that hinder their full and effective participation in society, ensuring equality for others. In doing so, the Convention lists forms of discrimination that disabled people experience includes allowing reasonable accommodation that corresponds to necessary and appropriate adjustments “(...) to ensure that persons with disabilities enjoy or exercise on an equal basis with others all human rights and fundamental freedoms” (art. 2).

The discrimination against disabilities, according to the Convention, should be fought according to some general principles, including respect for dignity, the autonomy of individual choice, accessibility, and equality of opportunity.

6. Lastly, with regard to employment, the UN tripartite agency bringing together governments, employers, and workers, the International Labour Organization (ILO), issued two documents devoted to discrimination, which

are the ILO Convention on Discrimination (Employment and Occupation) Convention 1958 (No. 111) and the related recommendation (R111). They require states to engage in national policies designed to assure equality of opportunity and treatment in respect of employment and occupation (including vocational training) to eliminate any discrimination.

Discrimination at work is defined by the Convention (art. 1) as any distinction, exclusion, or preference based on race, color, sex, religion, political opinion, national origin, or social origin. The result of the discrimination compromises equal opportunities or treatment in employment. Discrimination issues in employment may be determined by the member states concerned after consultation with representative employers, workers’ organizations, and other appropriate bodies.

In addition, the Convention refers to affirmative action. This should not be considered discrimination when, in agreement with the representative organizations of employers and workers, they represent special measures aimed at satisfying the particular needs of those in need, for reasons such as gender, age, disability, family responsibilities, social or cultural status, and of special protection or assistance.

Insights into the European Commitment to Nondiscrimination

European Union (EU) profoundly engages in eliminating all forms of discrimination within the territory of Europe. Accordingly, any discrimination based on nationality is prohibited by the Treaty of Rome (EU 1957), which entered into force in 1958 to establish the European Community, and the Treaty on the EU.

In addition, the Charter of Fundamental Rights of the European Union (EU 2000), declared in 2000 and which entered into force in 2009 along with the Treaty of Lisbon, devoted Chapter no. 3 to the principle of equality, listing the following rights: equality before the law; nondiscrimination; cultural, religious, and linguistic diversity;

equality between women and men; the rights of the child; the rights of the elderly; and integration of persons with disabilities. The right of non-discrimination (art. 21) is defined as “(…) forbids discrimination on grounds of sex, race, colour, ethnic or social origin, genetic features, language, religion or other belief, political opinion, membership of a national minority, property, birth, disability, age or sexual orientation.”

The European Commission (EC) further protects the principle of nondiscrimination through various directives, such as:

- Directive 2000/43/EC against discrimination on race and ethnic origin.
- Directive 2000/78/EC against discrimination at work based on religion or belief, disability, age, or sexual orientation.
- Directive 2006/54/EC equal treatment for men and women in matters of employment and occupation.
- Directive 2004/113/EC equal treatment for men and women in accessing and supplying goods and services.
- Directive Proposal (COM(2008)462) against discrimination based on age, disability, sexual orientation, and religion or belief beyond the workplace.
- L.N. 85 of 2007 European Union Act (CAP. 460) Equal Treatment of Persons Order, 2007.
- L.N. 461 of 2004 Employment and Industrial Relations Act, 2002 (ACT NO. XXII OF 2002), Equal Treatment in Employment Regulations, 2004
- L.N. 86 of 2007 European Union Act (CAP. 460) Equal Treatment in Self-Employment and Occupation Order, 2007.
- United Kingdom
 - Gender Goods Facilities and Services (GFS) Directive (2004/113/EC) – the Sex Discrimination Order 1976 (Amendment) Regulations (Northern Ireland) 2015.
 - Employment Equality (Sex Discrimination) Regulations (Northern Ireland) 2005.
 - The Employment Equality (Sex Discrimination) Regulations 2005.
 - Article 8 of Directive 2010/41/EU of the European Parliament and of the Council of 7 July 2010 on the application of the principle of equal treatment between men and women engaged in an activity in a self-employed capacity and repealing Council Directive 86/613/EEC.
 - The Employment Equality (Religion or Belief) (Amendment) Regulations 2003 SI n° 2828 of 06/11/2003.

National Transposition of EU Acts against Discrimination

To ensure full compliance with EU law, member states are required to align their national legislation with the requirement of the EU directives. According to the official website of the European Union Law (EUR-Lex 2022), most of national transposition measures on equal treatment and against discrimination have been recorded by Malta and the United Kingdom (before Brexit):

- Malta
 - L.N. 181 of 2008 Equality for Men and Women Act (CAP.456) Access to Goods and Services and Their Supply (Equal Treatment) Regulations, 2008.

Summary

Since the twenty century, the UN has issued several nondiscrimination conventions followed by several EU directives. The aim is to eliminate severe past discrimination usually suffered by minority groups, such as black people, women, homosexuals, less affluent classes, and disabled people, at the hands of the dominant groups.

While sovereign authorities (i.e., international organizations and their Member States) provide slightly different definitions and focus, the general consensus is that states must be firm in their statement of equality of rights of all people within their sovereign territory and must use all suitable means to protect the people against all forms of discrimination. To foster the achievement of

substantial equity among citizens, states are allowed not only to adopt laws providing positive discrimination in some cases but also temporary affirmative actions as remedy from severe past discriminations.

This contribution outlines the definition of nondiscrimination and related concepts including the main content of the declarations and conventions adopted by the UN and EU devoted to this topic.

External directors; Independent directors; Non-employee directors; Outsiders; Part-time directors

Definition

Non-executive directors appear in the academic literature under different names, such as external, non-employees, or part-time directors (Li et al. 2020; Mace 1979). They are not employees of the company and, therefore, are not involved in the daily management of the company. Although the concept of executive or internal directors is homogenous throughout the different world economies, the same is not true for external or non-executive directors (outsiders in Anglo-Saxon terminology), in which case the academic literature offers different definitions. This heterogeneity is closely related to the independent status of the directors with respect to the rest of the company's board members and its management team. Thus, it is possible to find different terminologies such as independent directors and external directors, both of them included in the generic category of external or non-executive directors. This matter is due to the fact that in Anglo-Saxon countries, where ownership structure is dispersed, large shareholders are not common and, therefore, the distinction between independent and outsiders is not necessary. However, countries framed within the civil law legal tradition (countries from Continental Europe and Latin America mainly) have concentrated ownership structures, and the presence of large controlling shareholders is commonplace (La Porta et al. 1999). In this context, the distinction between independent and external directors becomes of special relevance. For instance, a shareholder with a controlling interest in the firm can be an external director, but they could not be an independent director.

Those who have received the most attention, in the academic world as well as in the business and regulatory sectors, are independent directors – those who have no substantive relationship with the firm as employees or in any other capacity beyond their role on the board (Neville et al. 2018), that is, those without any connection to the company, its shareholders, or the rest of the groups with interests in the company (stakeholders).

Another type of external director is affiliate directors. In spite of not being part of the

management of the company, they have ties to the company or its members that prevent them from being considered independent. Thus, they can be representatives of workers or significant shareholders, who maintain contractual relations with the company (consultants, lawyers, etc.) (Samara and Berbegal-Mirabent 2018).

Key Issues

Most of the codes of good governance emphasize that boards must have a majority of external directors, giving special importance to the figure of the independent director (Cuomo et al. 2016; Garner et al. 2017). Probably owing to this widespread recommendation, the empirical evidence has found that companies in many countries have a lower proportion of executive directors than of external directors (Reguera-Alvarado and Bravo 2017; Terjesen et al. 2016).

From the perspective of the agency theory, external directors contribute efficiently to the good governance of the company, exercising effective control over the management team and its decision-making process (Fama and Jensen 1983). A greater proportion of external directors, especially independent directors, can reduce the likelihood that senior management will obtain private benefits at the expense of expropriating the wealth of the company's owners (Garner et al. 2017). External directors, as they are not an active part of the business management, have a greater degree of independence that makes them ideal candidates to exercise the supervisory function of the board of directors (Masulis and Zhang 2019). Based on these arguments, the most common proposal of the codes of good governance is to incorporate external directors, essentially independent, to be able to supervise the conduct of managers without a conflict of interest (Cuomo et al. 2016). These directors could be the voice of minority shareholders not present on the board, defend the feelings of other agents with interests in the company, or act as a barrier that limits managerial discretion. Although the logic of this proposal seems clear, as will be seen later, its empirical contrast is not so much (Stein and Zhao 2019).

From the perspective of the Theory of Resources and Capacities, external directors are also important, as they are a source of specialized knowledge and links with the outside for the company (Chen et al. 2016; Hillman and Dalziel 2003; Li et al. 2020), which validates them as good candidates to fulfil the advisory function of the board of directors (Dalton and Dalton 2005). In this sense, the directors who belong to multiple boards of directors are particularly relevant (Pfeffer and Salancik 1978). Likewise, the knowledge that these directors provide can be used by the management team in the formulation of their strategic decisions (Chen et al. 2016). External directors, thanks to their impartiality and independence from the management team, can have a positive impact on the board's decision-making (Dahya and McConnell 2005; Jenwittayaroje and Jiraporn 2019).

However, a board formed entirely by external directors could not efficiently develop the advisory function, given their lack of experience and knowledge about fundamental aspects of the company and its environment (Garner et al. 2017), not to mention the difficulty in acquiring it (Ford 1992). In this sense, Pettigrew (1992) argues that outsiders could have a negative impact on company performance if, due to their lack of information, they are not in a position to ratify decisions made by the most powerful members of the board. Moreover, the involvement of outsiders in business is often part-time (Siladi 2006; Stein and Zhao 2019), which implies, in words of Yusoff (2010), "that it is difficult for them to develop much more than a mere rudimentary understanding of the work of the company (Conger and Lawler 2009)". With these limitations, as Yusoff (2010) summarizes, they highly depend on the good will of management, especially the CEO, to obtain relevant and timely information about the company (Levräu and Van den Bergh 2007). In this same vein, Carter et al. (2010) argue that, since understanding the company's business is crucial for effective decision-making within the board of directors, the lack of this knowledge is of particular concern. Markarian and Parbonetti (2007) point out that the lack of information on the part of the independent directors could impede

an adequate decision-making (Yusoff 2010). Based on these arguments, a relatively new research current has postulated that having more non-executive directors does not necessarily mean improving the effectiveness of the board if they are not able to contribute anything (Garner et al. 2017; Masulis and Zhang 2019; Samara and Berbegal-Mirabent 2018; Stein and Zhao 2019).

When a board is supposed to be substantially independent, it is best to limit the CEO's participation in the committee that is responsible for nominating directors, so as to ensure that the latter's preferences are not closely aligned with those of the CEO, but rather with those of the shareholders (Garner et al. 2017). According to Raheja (2005), when the incentives of external directors are relatively better aligned with those of shareholders, a greater proportion of external directors is required. This result helps to explain why some studies have found that a higher proportion of external directors is associated with better business performance (Baysinger and Butler 1985; Jenwittayaroje and Jiraporn 2019). However, if outsiders are not truly independent and their incentives are aligned with those of executives inclined toward lower projects, boards with a higher proportion of external directors will be less efficient (Garner et al. 2017). This is consistent with Yermack (1996), Agrawal and Knoeber (1996), and Bhagat and Bolton (2013), among others, who report a negative relationship between the proportion of external directors and the company's performance. The joint interpretation of these arguments would help explain why the analyses that have not considered the characteristics of the companies studied have not found robust relationships between the proportion of external directors and corporate results (Li et al. 2020; Raheja 2005; Reguera-Alvarado and Bravo 2017).

Despite the advantages and disadvantages indicated, the existing empirical literature has documented mixed and inconclusive results about the relationship between external directors and company performance (Andrés and Santamaría 2018; Krause et al. 2017; Jenwittayaroje and Jiraporn 2019; Masulis and Zhang 2019; Uribe-Bohorquez et al. 2018). Therefore, the controversial relationship between the composition of the board and the performance of the company has

not provided conclusive evidence about the benefits of external directors over executives or vice versa, nor about the widespread good governance recommendations in favor of independents (Andrés and Santamaría 2018). While some studies observe a positive relationship between independence and results, others find them negative, not robust and even insignificant. Studies that have carried out a meta-analytical review of the previous literature have not shed light on this question either.

Future Directions

For years, regulators and academics believed that an effective board was a board with a majority of independent directors (Adams 2017). However, empirical evidence shows that it is hard to conclusively identify which board characteristics lead boards to be more effective (Adams 2017; Li et al. 2020). Nowadays, the extent to which any given director is truly independent and the conditions that they must meet to ensure their independence (Neville et al. 2018) is an open question that remains unanswered. Recent research points out that "the effectiveness of board independence is overstated because barriers, such as outside job demands and norms of deference, prevent independent directors from being effective monitors (Boivie et al. 2016). Similarly, Hambrick et al. (2015, p. 331) note that there is little evidence that director independence—in and of itself—accomplishes much" (Neville et al. 2018, p. 2541). Further research is needed to deepen our understanding of the effect of independent directors on the governance of organizations and to discover what are the most suitable characteristics that make independent directors effective enough to improve corporate governance (Reguera-Alvarado and Bravo 2017).

Nonfinancial information

Definition

The concept of “disclosure” can be defined as the process of information-sharing between

companies and stakeholders. Companies choose to “disclose” information as both an opportunity to engage in an effective way with stakeholders and as a necessity to comply with mandatory provisions (Pizzi et al. 2020). In recent years, companies worldwide have provided an increasing number of mandatory or voluntary disclosures. Specifically, the main innovation has been the quick growth of nonfinancial disclosure (Dumay et al. 2015). The quick growth of the average number of nonfinancial reports firms provide has been encouraged by both the increasing attention paid by stakeholders to nonfinancial themes and the introduction of new forms of regulation. Furthermore, many firms have started to disclose nonfinancial information through more sophisticated tools like Integrated Reports and social media (Lodhia and Stone 2017). Finally, the explicit requirement in SDG 12.6 of more disclosure in order to achieve sustainable development has attracted further attention to disclosures from academics and practitioners.

Introduction

Despite the existence of several factors that impact firms’ orientation toward sustainability, the disclosure of nonfinancial information is typically related to the desire to increase stakeholders’ trust (Dumay 2018; Venturelli and Caputo 2017). In fact, several studies have revealed how stakeholders are typically skeptical about firms’ behaviors (Hill et al. 2009) due to the existence of unethical behaviors behind the adoption of sustainable practices in cases such as “greenwashing.” Prior evidence has shown that managers typically share only favorable information with stakeholders (Bertomeu and Magee 2015). Furthermore, managers could overestimate their sustainability achievements due what benefits them personally in terms of reputation and rewards.

Nonfinancial disclosure represents a tool to mitigate these risks. Nowadays, an increasing number of firms have started to disclose nonfinancial information through nonfinancial reports (KPMG 2017). Furthermore, some contexts like

the European Union Member States have started to introduce new forms of regulation in their legal systems to increase the overall degree of transparency about firms' contribution to sustainable development (La Torre et al. 2018). However, scholars have observed how the introduction of mandatory provisions about nonfinancial disclosure needs a cultural change in order to produce positive externalities (Ackers and Eccles 2015). Specifically, these studies reveal how the concepts of "quality" and "quantity" in nonfinancial disclosure are different.

Antecedents and Consequences of Nonfinancial Disclosure

Academics have looked for ways to increase the value and relevance of nonfinancial disclosure for stakeholders and policymakers. Specifically, these studies have been identified the determinants that impact the quality of non-financial reporting. Additional studies have analyzed the impact of nonfinancial disclosure on financial performance.

As observed, the concepts of "quality" and "quantity" in nonfinancial disclosure are different (Huang and Watson 2015; Beretta and Bozzolan 2008). However, academics' opinions about the relationship between these two different factors diverge. Specifically, some authors have proposed that the quantity of information provided could be a proxy of nonfinancial disclosure quality (Venturelli and Caputo 2017). However, other academics highlight how comprehending a non-financial disclosure's quality requires a contextual analysis of items not related to quantitative indicators (Beretta and Bozzolan 2008). Furthermore, many empirical studies have shown how non-financial disclosure quality could be influenced positively by items not related to the number of indexes disclosed. Specifically, items like third party assurance, the adoption of international standard setters, prior experience in nonfinancial reporting, and board characteristics are likely to increase the quality of a business's nonfinancial disclosure (Daub 2007; Dilling 2010; Venturelli et al. 2019).

The relationship between nonfinancial disclosure and corporate financial performance has been widely explored by academics (Ameer and Othman 2012; Omran et al. 2019). These studies have incorporated different perspectives in order to evaluate the "value relevance" of non-financial disclosure. However, prior studies have shown that the link between the two factors is influenced by endogenous and exogenous variables including the characteristics of the company and the geographical context.

The Role of Disclosure on Sustainable Development Goals

In order to achieve a high degree of worldwide sustainable development, the United Nations (UN) has signed the Agenda 2030, which establishes an agreement between UN Member States to define a set of Sustainable Development Goals (SDGs) to achieve before 2030. Specifically, the SDGs consist of 17 goals and 169 targets about different themes related to the macroconcept of sustainable development. Unlike the previous Millennium Development Goals (MDGs), the SDGs require an active contribution from the private sector.

The achievement of SDGs is strongly related to the concept of nonfinancial disclosure. Specifically, disclosure plays a central role due to the need to identify evaluation tools able to describe the private sectors' impact on the SDGs. The UN recognizes this need through an explicit reference to the topics in SDG 12. SDG 12.6 requires Member States to "encourage companies, especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle." Furthermore, the UN identifies the "number of companies publishing sustainability reports" as an evaluation indicator. However, despite their explicit requirement of more disclosure from the private sector, the preliminary studies about the integration of SDGs in nonfinancial disclosures reveal that only a few firms voluntarily adopt this type of information in their reports (Rosati and Faria 2019).

Summary

During the last few years, firms have started to introduce new items in their strategic planning in order to favor these beneficial processes. However, nonfinancial scandals and the existence of unethical behaviors behind the introduction of these practices have had a negative impact on stakeholders' trust. According to the evidence, the disclosure of nonfinancial information represents an effective tool to repair, maintain, and regain trust from stakeholders. Furthermore, the necessity to contribute effectively to the SDGs has imposed on managers the need to adopt new forms of reporting in order to disclose their nonfinancial information.

Nongovernmental Organization

Agnieszka Pacut
Cracow University of Economics, Cracow,
Poland

Synonyms

[Independent sector](#); [Nonprofit organization](#); [Public benefit organization](#); [The third sector](#); [Voluntary organization](#)

Definition

The term “non-governmental organizations” (NGOs) covers a variety of organizations, depending on the legal forms, sources of funding, and type of activities, that operate beyond the boundaries of the market and the state. The term

“the third sector” highlights their distinctiveness and difference from the public and commercial sectors and refers to the voluntary engagement of individuals based on differentiated values (Salamon and Anheier 1992; Vakil 1997).

NGOs are social organizations being active in the private, public, and civil society (Mercer 2002). NGOs undertake activities that benefit the society, or a significant part of it, and act toward a mutual benefit while satisfying specific needs of the members of the organization.

According to the structurally operational approach, the following attributes describe the role of NGOs (Salamon and Anheier 1992; Salamon et al. 1999): (1) formal character (in institutional dimension and in structure – procedures, rules and sustainability, and internal organization); (2) private (independent, institutionally separate from the state, and free and unrestricted in its decisions and elections); (3) nonprofit distributing; (4) self-governing (own internal management and control systems); and (5) voluntary (membership not obligatory; voluntary activities that do not exclude the possibility of using paid staff).

The term NGO describes a range of organizations from watchdogs and aid agencies for development and policy organizations (Young and Dhanda 2012).

NGOs are becoming important players on national and international level (Anheier and Kendall 2001). Their activities contribute to social, economic, and political developments.

The Emergence and Role of NGOs

Increased interest in nongovernmental organizations (NGOs) and the development of the theoretical background took place in the second half of the twentieth century. The term NGOs appeared in international literature in 1945 through the United Nations (Martens 2002; Vakil 1997). In the following years, the role of NGOs has gained importance worldwide. It was caused by several complementary factors. First, there were democratization, decentralization, and the emergence of civil society. Second,

attention should be paid to the growing demand for information in the society as well as to the development of information society tools. Third, there has been an increase in the number and types of organizations with different functions and powers in nation-states and internationally. These processes have been accompanied by the transformation of the public sector and a decline in public confidence in decision-makers (McGann and Johnston 2005).

The NGOs are recognized as important actors on the local, national, and international level. The NGOs play several important operational roles in the social, economic, and political dimensions (Anheier and Seibel 1990).

The key NGOs functions are service delivery, educational provision, and public policy advocacy (Stromquist 2002). NGOs' activities can also be considered as: (1) vanguard (introducing innovative solutions, experimenting in the areas in which they operate), (2) advocate (representing and publicizing the interests of discriminated groups), (3) guardian of values (promoting and protecting values that contribute to pluralism and democracy), and (4) provider of public goods and services (Kramer 1981). The main activities and roles of NGOs cover the following: (1) implementers (the mobilization of resources to provide goods and services to people), (2) catalysts (inspire, facilitate, or contribute toward developmental change among the other actors at the organizational or the individual level), and (3) partners (build meaningful partnership relationships with other sectors) (Lewis 2007, pp. 68–76). The third sector organizations are an important mechanism for meeting individual and collective needs as well as promoting empowerment for sustainable community development (Nikkhah and Redzuan 2010). The NGOs contribute to social development by facilitating social development achievements (measured by the Human Development Index). They also promote sustainable development (focusing on the social and environmental impacts of economic activity including relations with stakeholders) and sustainable consumption (educating households to change their consumption attitudes and behavior) (Young and Dhanda 2012) (► [Sustainability](#)).

However, the activities of nongovernmental organizations are characterized by specific problems. The nonprofit sector has inherent limitations: philanthropic insufficiency, philanthropic particularism, philanthropic amateurism, lack of finance (Salamon 1987), or other governance problem concerning accounting and accountability (Cordery et al. 2019; Hind 2017).

Issues

The academic discourse on NGOs in the 1990s focused on the conceptual and theoretical foundations to explain and describe their activity and was targeted to academics, practitioners, and public decision-makers. The scope of the analysis included background, history, concepts, theory, statistics, behavior, management, and policy (Anheier 2005). At the same time, issues such as the legal framework, management (leadership, planning, and management), income generation, government contract, accountability, and evaluation were further research directions (Herman et al. 2011; Ott 2001; Powell and Clemens 1998). In other words, the research of third sector organizations focused on institutional emergence, NGOs operation (internal governance and organizational structures and strategies, including their relations with stakeholders), and the results obtained (Johnson and Prakash 2007).

The following questions were of interest to NGO researchers (Halfpenny and Reid 2002): Which organizations make up the third sector? How is the third sector resourced? Why do NGOs exist? How do they differ from other organizations? What are the relationships of NGOs with other sectors (stakeholders)? (► [Stakeholders](#)).

The theoretical analysis refers to a range of disciplines – including law, economics, political science, public administration, and various topics.

Future Directions of Research

There are many reasons to continue the research on NGOs. On the one hand, it is necessary to point out the process of transformation that concerns the

modern democratic state. On the other hand, there is an increase in the number and types of nonprofit organizations, as well as their greater dependence on public income. In addition, there has been a significant increase in privatization and commercialization of public services. This has led to convergence and the blurring of sectoral boundaries (Kramer 2000).

Future research of NGOs should address the following: (1) accountability and evaluation of activity and results of NGOs (forms, processes, and mechanisms of NGOs accountability by placing variety groups of stakeholders at the center of the analysis (McDonnell and Rutherford 2019); (2) new ways of inter-sectoral cooperation in solving domestic and international problems (analysis of models linking the public and NGOs in the context of diverse state policies, increase in demand for social services, and emergence of new models of public governance) (Pollitt and Bouchaert 2011), as well as the analysis of NGOs' interactions with commercial organizations (especially multinational corporations) in the era of globalization; and (3) hybridization and economization of NGOs' activities (analysis of strategies of mobilizing resources by NGOs, including the creation of social enterprises as a form of gaining financial resources, independence from the public sector, and inclusion of beneficiaries and stakeholders in the activities of organizations) (Dees 1998; Eikenberry and Kluver 2004) (► [Social Entrepreneurship](#)).

Summary

In recent years, the importance of NGOs has increased at the local, national, and international levels (Teegen et al. 2004). They perform diverse functions in the state and society (Salamon 2001). They offer innovative ways of solving social problems (social innovations) as well as they anticipate and prevent the appearance of new problems. At the same time, they are involved in the implementation of public services, supporting and complementing the activities of public decision-makers. NGOs are subject to quantitative, but above all qualitative changes in the world

(Kramer 2000). Issues concerning the efficiency and effectiveness of organizations' management, as well as their entrepreneurial and innovative behavior, are growing in importance (Andersson and Self 2015).

Definition/Description

Portuguese standard for the development and implementation of the social responsibility management system (SRMS). This is a standard detail requirement that aims to facilitate the organization with the commitment of the social responsibility, based on sustainability issues and actions in the context of the sustainable development challenges.

Introduction

The Brundtland Report (1987, p. 20) argues that the “sustainable development is not a fixed state of harmony, but rather a process of change,” in which “exploitation of resources, direction of investments, orientation of technological development,

and institutional change are made consistent with future as well as present needs.” This argument allows to understand the relevance of the planning, doing, checking, and acting on the SRSM system using the Shewhart cycle (1939), or Deming cycle (1982), renamed in 1950, as the methodology to implement and to assess the system and subsequent certification process.

At Portuguese level, the NP 4469 is the national standard published by the *Instituto Português de Qualidade* in 2008 (IPQ 2008b) and the updated version in 2019 (IPQ 2019). The acronym “NP” means *Norma Portuguesa* (in English: Portuguese standard). The *Instituto Português de Qualidade* (in English: Portuguese Quality Institute) is the Portuguese public body that approves technical regulations.

At the international level, following the achievement of the implementation of standards promoted by the International Organization for Standardization (ISO), organizations, all over the world, started looking for guidance to develop certifications on social responsibility strategies on the organization. At the same time, researchers, as Castka and Balzarova (2008), provide insights on the Working Report on Social Responsibility from the first version of ISO’s Advisory Group on Social Responsibility published in 2004. In Portugal, David Crowther consolidates a research team with R. Abreu and F. David who start to research about empirical evidence of corporate social responsibility in Portugal (Abreu et al. 2005).

Indeed, in Portugal, the first steps of a Portuguese standard were taken in June 2004, when the Portuguese Quality Institute nominated the Portuguese of Business Ethics Association as a sectorial standardization body of the Portuguese Quality System in fields of business ethics and social responsibility.

In March 2005, the Sectorial Standardization Body of the Portuguese Business Ethics Association formed a Technical Committee on Social Responsibility – CT 164 – with the objective to create a Portuguese standard for social responsibility for organizations.

This CT 164 was constituted by a set of entities, recognized by the ISO like unions (in Portuguese

União Geral de Trabalhadores or Workers General Union), consumers, government (i.e., INETI, DGE, IEFP), services, nongovernmental organizations (NGOs) (in Portuguese *Associação Portuguesa de Ética Empresarial* or Portuguese Business Ethics Association), and industry. In 2021, the representation for each group is as follows: industry and commerce (A) with 27.03% and SME (A1) with 5.41%, administration (B) with 21.62%, work (D) with 8.11%, universities and technological centers (E) with 8.11%, application of standards (F) with 21.62%, and NGOs with 8.11%. Those without representation on the CT 164 are as follows: consumers (C), social groups of consumers (C1), and environmental organizations (IPQ 2021).

In this sense, the NP 4469 standard is an international alignment with the ISO 26000: 2010 standard: guidance on social responsibility that aims to provide guidance (ISO 2010, p. vi) and maximize an organization contribution (ISO 2010, p. ix).

The methodology used to build the standard was technical teams and plenary sessions, based on the research promoted by the consultation process subdivided by five forums about ethics and social responsibility between 2005 and 2007, online survey made by Portuguese Business Ethics Association between April and July of 2006, and public survey between September and October of 2007.

The NP 4469-1: 2008 (IPQ 2008b, p. 11) was the Portuguese answer to organization's needs about the SRMS that has been defined as the system that enables an organization to develop and implement policies, objectives, and coherent actions, considering the legal, regulatory, and others which the organization subscribes. It applies to aspects of social responsibility that the organization identifies as those who can control and those it can influence.

In this context, this standard is applicable to all types of organizations, dimensions and geographical location, and cultural and social conditions. Its main goal is to support organizations that implement a SRMS to promote the connection to all the stakeholders through a relationship of mutual partnership, achieving mutually satisfactory results (Ramalho et al. 2009).

According to NP4469, the aspects that need to be considered for the implementation of social responsibility (SR) system are as follows: get the commitment of top management to the importance of SR; involve all employees in participation and collaboration in a new culture; integrate the (SR) management system into the organization's strategy; obtain commitment from the entire organization; analyze the current situation of the socio-environmental practices; develop an action plan, including indicators appropriate to the organization; evaluate the action plan; implement the continuous improvement of the SR Policy; and promote communication stakeholders.

In 2010, IPQ published the Portuguese standard NP 4469-2: 2010 SRMS – Part 2: Guidance for Implementation (IPQ 2010).

This standard supports the application of NP 4469-1: 2008 and allows any organization to develop and to implement the social responsibility policy, principles, objectives, activities, and actions, considering the legal requirements and others that the organization subscribes.

The NP 4469-2: 2010 interprets each requirement of the NP 4469-1: 2008, serving as a guide for its implementation through the presentation of real examples and a self-diagnosis in each requirement.

The updated version was published on January 15th of 2019 of the Portuguese standard NP 4469: 2019 – “Social Responsibility Management System: Requirements and guidelines for its usage” which aims to establish organizations' commitment to sustainability issues.

This standard is IPQ (2019) and it is a contribution to the organizations' response to the 2030 Sustainable Development Agenda, preparing them for new challenges and trends in the global economy and the use of innovative opportunities and solutions, responding to the increased demand, and consequently improving competitiveness. It, also, improves relations with stakeholders, increasing credibility and confidence in value chains and continued presence in demanding environmental, social, and governance markets (APCER 2019).

The requirements of the standard (IPQ, 2019) are organized into ten sections develop and

implement of the SMRM. The starting section is the summary of this standard entitled the “Preamble,” where is explanations about the evolution on time of this standard.

Section 0 “Introduction” has been divided in two complementary subsections: framework of the social responsibility on organizations and the social responsibility management model.

Section 1 “Objective and field of application” defines the requirements for all public and private organizations, several types, dimensions and even the juridic personality to establish, to implement, to maintain, and to improve the SRMS.

Section 2 “Normative reference” is fully aligned with the NP ISO 9001: 2015 (IPQ 2015a), NP ISO 14001: 2015 (IPQ 2015b), NP 4397: 2008 (IPQ 2008a), ISO 26000: 2010 (ISO 2010), and ISO 45001: 2018 (IPQ 2018).

Section 3 “Terms and definitions” defines 55 key terms and details each one, and some of them have specific notes to justify it with source.

Section 4 “Organizational context” defines requirements related with the definition of the organization’s values and principles, identification of stakeholders, and determination of organization’s scope. Indeed, this section is subdivided into four subsections: understand the organization and its distinctive context, understand the needs and clarify expectations of stakeholders (values and principles), define the scope of the SRMS, and develop the SRMS and verify appropriate documented information.

Section 5 “Leadership” establishes requirements related with SR commitment at the top management, the definition of the social responsibility policy, and roles, responsibilities, and authorities.

Section 6 “Planning” determines requirements related to actions to manage risk-based and opportunity-based approach, set the social responsibility objectives, and develop plans to achieve them.

Section 7 “Support” defines requirements associated with resources for performance of the SRSM system, encourage skills and the promotion of the awareness, manage SR communications, and control the SR documented information to establish, implement, and maintain the liability of the management system.

Section 8 “Operations” describes, on the organizational context, the operational planning and control and prepare the emergency response to social responsibility needs.

Section 9 “Performance assessment” defines actions to monitor, measure, analyze, and assess the SRMS, as well as requirements to internal audit and management review of the SRMS.

Section 10 “Improvement” specifies requirements related to nonconformities, corrective actions that must be taken, and improvement opportunities of the performance assessment in the social responsibility management system.

A comparative analysis of the NP 4469: 2008 with the new version of NP 4469: 2019 is reorganized, specifically in section 4 related with the internal and external organization context. The terms of the context include technological options, business operational resources, and social and environmental issues, among other aspects. There are no significant changes with the definition of values and principles of social responsibility. However, ethical principles must be part of ethical conduct in activity development and transparency in the relationship with stakeholders.

In section 4.1.1.2 “Principles” of the NP 4469 (IPQ 2019) that is related with section 3.2.2 “Principles” of the NP 4469 (IPQ 2008b), there is reorganization of this requirement, based on the following 11 principles: first principle, compliance with the law, collective regulation instruments, and applicable regulations; second principle, respect for internationally recognized conventions and declarations; third principle (new in the updated version), ethical conduct in the development of the activity in accordance with accepted principles of correct or good conduct; fourth principle (increase three levels in the updated version), transparent action, information sharing, and open behavior within the relation of stakeholders; fifth principle (decrease one level in the updated version), recognition of the right of interested parties to be heard and the duty of the organization to react; sixth principle (decrease one level in the updated version), recognition of the direct and indirect aspects of social responsibility of the organization, taking into account the entire

life cycle of its products; seventh principle (decrease four levels in the updated version), adoption of the precautionary principle; eighth principle (decrease two levels in the updated version), privilege to prevent pollution at source; ninth principle (decrease one level in the updated version), accountability for the organization’s actions and omissions and accountability for its conduct in the face of the legitimate concerns of interested parties; tenth principle (decrease one level in the updated version), integration of aspects of social responsibility in the organization’s management systems and in its decision-making process; and 11th principle (decrease one level in the updated version), non-regression, that is, not using the provisions of this standard as a basis for reducing the levels of performance in social responsibility already achieved by the organization.

Another important change has been the loss of several concepts that help the organization to identify stakeholders advising to consider the scale, nature, and geographic location of the organization’s products and activities. In addition, Fig. 1 that allows to identify stakeholders is subdivided based on five criteria, such as:

Figure 1 shows the stakeholder identification based on the following:

- 1. Relation – stakeholders with whom the organization has, or may have in the future, legal, financial, or operational obligations in the form of regulations, contracts, policies, or codes of

conduct (i.e., employees, local authorities, unions) (IPQ 2008b, p. 16).

- 2. Influence – stakeholders that influence or may influence the organization’s ability to achieve its objectives, regardless of whether its actions are aimed at facilitating or hindering its performance (i.e., local authorities, shareholders, and pressure groups) (IPQ 2008b, p. 16).
- 3. Proximity – stakeholders with whom the organization interacts most, including internal stakeholders (i.e., employees and shareholders), stakeholders with long-standing relationships (i.e., business partners), stakeholders from whom the organization it depends on day-to-day operations (i.e., local authorities, local suppliers, or temporary work companies), and stakeholders who live in the neighbor of the organization’s plant (permanent or temporary) (IPQ 2008b, p. 16).
- 4. Dependency – stakeholders who are directly or indirectly dependent on an organization’s activities and products in economic or financial terms (i.e., single employer in the locality or single supplier of goods or services) or in terms of regional or local infrastructure (i.e., schools, hospitals) and to satisfy basic needs (i.e., supply of medicines, water, or electricity). Account should be taken of the degree of dependence on stakeholders, considering the stakeholders who are most dependent on the organization (i.e., employees and their families, customers who depend on the organization’s products for their health, safety, or survival of suppliers for whom the organization is the dominant customer) (IPQ 2008b, p. 16).
- 5. Representation – stakeholders who, through legal rules, statutes, customs, or culture, can legitimately claim and represent other individuals (i.e., representatives of the local community and consumers, union associations, NGOs). This includes representatives of stakeholders without a voice (i.e., environment and future generations) (IPQ 2008b, p. 17).

Stakeholders	Internal	External	Relation	Proximity	Influence	Dependency	Representation
S1		X	X	x		x	X
S2	X		x	x	x	x	x
..							

Legend: S1 – Suppliers; S2-employees

NP 4469: Portuguese Social Responsibility Standard,
Fig. 1 Stakeholder identification. S1, suppliers; S2, employees

Section 4.3 “The scope of the social responsibility management system” identifies limits and their applicability and includes all activities

promoted directly by the organization and all places where its activities are developed.

In Section 5 “Leadership,” changes are identified in relation to the previous version, namely, in requirements for the demonstration, by the top management, of the leadership and commitment in relation to the management system (5.1). In the current version, there is a reinforcement of the need for compatibility of the policy and objectives with the strategic orientation and the context and in the orientation toward the results and effectiveness of the social responsibility management system. This section also includes the addition of requirements for top management to demonstrate leadership and commitment.

In Section 5.3 “Organizational roles, responsibilities, and authorities,” corresponding to point 3.6.1.2 “Responsibility and authority” of the previous edition, in addition to the existing requirements, top management should assign responsibility and authority to ensure that the integrity of the social responsibility management is maintained when changes are planned and implemented in the respective system. Like other management system standards, NP 4469 also no longer must appoint a management representative for this system.

The organization must determine the actions to address risks and opportunities, related to aspects of social responsibility (6.1.2) and compliance obligations (6.1.3). In determining the significance of aspects of social responsibility (6.1.2), the following should be considered: the views of significant stakeholders, new or planned developments, new or modified activities or products, and irregular conditions and potential emergency situations.

Section 7 “Support” separates requirements relating to competence and awareness, treating them in different subsections. Section 7.5.3 “Information Control” addresses the issue of managing access to documentation information, and the organization must decide on the authorization levels to consult or change the documented information.

Section 8 “Operational” details the need of the organization to establish, to implement, and to maintain one or more procedures to identify

emergency situations and potential accidents and, also, to give information and to promote education to relevant stakeholders and employees that work under its control.

Section 9.2 “Internal audit” provides guidance to the organization that must consider the importance in social responsibility of the processes of the audit program or any change required due to risk-based and opportunity-based approach determined in terms of social responsibility and previous audits.

As common best practice of the ISO, this management system is possible to be certified and, in this sense, the organization publicized its certificate the implementation and certification through the NP 4469 SRMS bring several benefits to organizations, as the following examples: contribution to sustainable development and easy access to new markets, by increasing demand for socially and environmentally responsible products; greater credibility and reputation in the market; greater confidence in the value chain and the final consumer; competitive advantages and better relationship with all stakeholders; attracting and retaining talent, increasing productivity, reducing absenteeism, and reducing costs related to accidents and illnesses; better management of natural resources, with the respective reduction of associated costs; and integration with other management systems (APCER 2019).

Appendix A of the NP 4460-1 (IPQ, 2007) lists several standards and relations between them which allow the organization to implement the four management systems in a global strategy. This standard is characterized by being a management system based on the Plan-Do-Check-Act (PDCA) cycle, and the structure is fully aligned with the ISO 9001: 2015 (IPQ 2015a), ISO 14001: 2015 (IPQ 2015b), and ISO 45001: 2018 (IPQ 2018). Indeed, the justification of this alignment is presented on this appendix.

Appendix B of the NP 4460 lists the aspects of social responsibility to be considered as guidelines for the implementation, and the organization is responsible for identifying the requirements applied to this activity, identifying their significance, and involving its significant stakeholders in the process. These guidelines go from corporate

governance, human rights, labor practices, environment, operational practices, consumers, and society development.

All standards are based on the International Standards Catalogue (ICS) from ISO (2021). This standard is related with other standards on the classification “03. Services. Company organization, management, and quality. Administration. Transport. Sociology,” and the field is “100. Company organization and management. Management systems” and “99. Other standards related to company organization and management.” Also, “13. Environment. Health protection. Safety,” on the field “020. Environmental protection” and “10-Environmental management, including certification and audit, and management systems (EMS).”

For all the reasons, the NP 4469 differs from other social responsibility standards by developing an orientation for stakeholders, for awarding a set of social responsibility principles coherent to main interests and expectations of stakeholders, as it allows the implementation of a management system to provide a single model for the pillars of sustainable development (Ramalho et al., 2009).

Summary

The NP 4469 standard defines the requirements for the social responsibility management system, aims to guide the organization to be more socially responsible, and encourages distinctive practices that enable differentiation and added value for it. These requirements develop and implement the social responsibility policy, objectives, and coherent actions, considering the legal, regulatory, and other requirements that the organization must follow to develop its economic activity.

Additionally, the concept of social responsibility shows a high potential driver of sustainable development (IPQ 2008b, 7). Thus, SRMS assumes itself as a strong risk-based management tool and instrument to distinguish organizations in the strong dynamic market that carried a social, environmental, and economic challenges, to contribute to the sustainable development. In this sense, an SGRS implemented in accordance with

NP 4469 aims to encourage and guide organization’s responsible action in the context of sustainable development challenges (IPQ 2008b, 8).

For the implementation of the NP 4469, social responsibility is understood as the voluntary actions of the organization with a view to creating and to maximizing their positive impacts, as well as reducing or eliminating their negative impacts.

Furthermore, when an organization implements and promotes the certification of the SRMS assumes the objective of continuously improving its performance in this area and, consequently, developing and consolidating relationships of trust and credibility between stakeholders.

This standard is applicable to any type of organization that plans, implements, controls, and improves the social responsibility management system, regardless of its size, sector of activity, and organic structure, among other differences.

Introduction

The Occupational Safety and Health Administration (OSHA) is a US public agency. As part of the Department of Labor, OSHA is responsible for issuing and enforcing occupational safety and health standards.

Since OSHA's establishment in 1970, the number of workers who have suffered an accident, contracted a disease, or even died at work in the United States has decreased by more than 65%, although the employment has almost doubled (OSHA 2018). Undoubtedly, OSHA has significantly contributed to the reduction of work-related injury, illness, and deaths in the United States, by performing different types of activities.

OSHA prepares and issues standards to help employers prevent hazards in the workplace. It also conducts on-site inspections to verify

compliance with such standards and issues penalties for those who breach the imposed rules.

In addition, OSHA promotes cooperative programs through which it increases employer and employee awareness and understanding of occupational hazards, so that they can improve how they manage such risks.

OSHA systematically interacts with employers, workers, business associations, unions, safety and health professionals, and public organizations, including the National Institute for Occupational Safety and Health.

The History

OSHA was founded at the beginning of the 1970s to deal with the serious problem of dangerous working conditions to which workers were subjected across the United States. Given the complexity and sensitivity of the matter, the creation of OSHA received the bipartisan support of the Congress and represented the culmination of decades of reforms. OSHA was created by the Williams-Steiger Occupational Safety and Health Act of 1970 (OSH Act), which was signed into law by President Richard N. Nixon on 29 December. Four months later, on 28 April 1971, OSHA was officially established and George Guenther was appointed as Assistant Secretary, OSHA's highest officer (OSHA 2010).

During the first 2 years of activity, OSHA adopted interim standards of safety and health in the workplace, known as "consensus standards": in other words, it implemented existing recommendations from professional organizations and it recognized rules adopted under old laws, which were already used in the private sector in the United States.

In January 1972, the OSHA Training Institute was established to train OSHA compliance officers (i.e., inspectors) and safety personnel of both private sector and federal governments.

In the meantime, OSHA began to draft its own standards. The first OSHA standard was issued in June 1972 and focused on the protection of workplaces from asbestos. Following this, OSHA issued and updated many other standards for the

prevention of occupational injuries and illnesses in different sectors and in relation to a number of hazards. Table 1 presents a non-exhaustive list of OSHA standards, which pertain to four industries: Construction, Maritime, Agriculture, and General Industry (this latter referring to all industries not included in the previous three).

In 1972, OSHA also approved the South Carolina and Oregon State plans: for the first time, OSHA's protection was extended to cover state and local government workers.

Occupational Safety and Health Administration, Table 1 Main OSHA standards and regulations

Asbestos (June 1972)	Chemical processes (February 1992)
Construction safety (November 1972)	Working in confined spaces (January 1993)
Carcinogens (January 1974)	Fatal falls in construction (August 1994)
Vinyl chloride (October 1974)	Asbestos (August 1994 – update)
Coke oven emissions (October 1976)	Logging operations (October 1994)
Commercial diving operations (July 1977)	Construction scaffold safety (August 1996)
Cotton dust (June 1978)	Methylene chloride (January 1997)
Hearing conservation (January 1981)	Marine terminals (July 1997)
Hazard communication on chemicals (November 1983)	Healthcare (January 2001)
Ethylene oxide (June 1984)	Fire protection in shipyard employment (September 2004)
Ground-fault circuit interrupters (July 1986)	Hexavalent chromium (February 2006)
Field sanitation in agricultural establishments (May 1987)	Walking/working surface safety (May 2010)
Benzene (September 1987)	Cranes and derricks (August 2010)
Grain handling (December 1987)	Hazard communication on chemicals (March 2012 – update)
Laboratory safety (January 1990)	Construction safety (April 2014 – update)
Bloodborne pathogens (December 1991)	Walking/working surface safety (November 2016 – update)

Created by this Author

The year 1975 saw the launch of OSHA's On-site Consultation Program to assist small businesses exposed to a high level of occupational hazards. The program, which is still running, helps small employers understand, identify, and manage safety and health risks in their workplace; it also ensures training of workers and supervisors. The success of this program is attested by the huge number of firms involved, with over one million site visits since the 1970s.

In 1978, OSHA inaugurated the New Directions Program (now Susan Harwood Grants), through which it has supported the training and education of over one million employers and workers to date.

The year 1980 was a milestone in OSHA's history: an executive order by US President Jimmy Carter imposed OSHA coverage for millions of federal workers, in addition to the private sector employees who were already protected by the Agency's regulations and standards.

To encourage employers to rethink and strengthen the mechanisms for the prevention of workplace accidents and occupational diseases, OSHA introduced certain Voluntary Protection Programs in 1982. Thanks to these programs, the businesses with the most advanced occupational risk management systems have been flagged as positive examples to be emulated by other employers.

OSHA took a further step in the improvement of safety and health at the workplace in 1989, when it published voluntary guidelines to stimulate the adoption of more effective programs in US businesses and public agencies.

In its almost 50 years of life, OSHA has often intervened to supervise and ensure employee health and safety in exceptionally dangerous circumstances. One might as well say that OSHA's history has sadly been caught up in industrial disasters since 1975, when Americans realized the toxic nature of kepone, a chemical substance produced by a small firm in Virginia and then dumped into a river. The kepone case highlighted the terrible impact of chemical products on workers (57 in this case were permanently affected), other individuals, and the environment.

Faced with this situation, OSHA became even more aware of the importance of its role in the protection of human health and wildlife; it thus renewed its efforts to develop further and broaden its expertise.

Ten years later, OSHA ordered more detailed inspections in all US chemical plants manufacturing or processing methyl isocyanate, the substance that had recently caused thousands of deaths in the Bhopal disaster in India. This serious episode also prompted OSHA to intensify inspections in all chemical factories.

Similarly, in 1987, the L'Ambiance Plaza disaster in Connecticut, where a 16-storey building under construction completely collapsed killing 28 workers, drove OSHA to adopt stronger regulations for the construction industry.

In 1989, after the notorious Exxon Valdez oil spill into the Gulf of Alaska, OSHA sent inspectors to monitor worker protection and imposed health and safety training. In the same year, a series of explosions at the Phillips petrochemical plant in Pasadena, Texas, provoked the death of 23 workers. This tragedy highlighted the need for new regulations, which were introduced through the publication of the Process Safety Management standard in 1992.

Following the Imperial Foods fire in North Carolina, which killed 25 poultry workers who had been trapped in the building, OSHA ran investigations and ordered the adoption of more stringent rules. This led North Carolina to approve a new State Plan for occupational health and safety in 1992.

In 2001, OSHA officers supported and monitored the workers engaged in the clean-up and recovery operations following the September 11 terroristic attacks.

A few years later, OSHA imposed the largest fine in its history: the sanction was applied to BP after an explosion in a Texan oil refinery in 2005 that killed 15 workers and injured 160. This tragic event also led to an increase in inspections in all American refineries.

In 2008, OSHA started to focus on the hazards in processing industrial combustible dust. In particular, OSHA's concern had been raised by several explosions, including in the Imperial Sugar

Refinery in Georgia, which caused the death of 14 workers and injuries to another 30.

Finally, OSHA had a key role in the protection of workers employed in the clean-up following the catastrophic BP Deepwater Horizon oil spill in the Gulf of Mexico. The accident, caused by an explosion, occurred in April 2010, leading to the death of 11 workers and creating one of the worst environmental disasters ever. At the time, OSHA operated as part of the coordinated federal response to support workers: it conducted 4200 on-site visits and analyzed over 7000 air samples collected at clean-up areas, both on- and off-shore. Moreover, it reviewed 90,000 air samples taken by other federal agencies and by BP.

Mission/Objectives/Focus Areas

OSHA aims to “ensure safe and healthful working conditions for working men and women by setting and enforcing standards and by providing training, outreach, education and assistance” (OSHA 2018).

Obviously, worker protection requires the employer’s strong awareness of work-related hazards and serious commitment to their effective and continuous prevention and management. For this reason, OSHA promotes the circulation of information on occupational injuries and illnesses, supports education and training of both employers and workers, provides occupational safety and health standards, and runs on-site inspections to verify the implementation of such standards.

OSHA’s regulations protect most private sector workers and some public sector workers in the 50 States, but also in some territories under federal authority, including the District of Columbia, Puerto Rico, the Virgin Islands, American Samoa, Guam, Northern Mariana Islands, Wake Island, Johnston Islands, and the Outer Continental Shelf Lands. More specifically:

a) OSHA covers private sector employers and workers either directly or indirectly. In the first case, OSHA coverage operates under the rules released by Federal OSHA itself, while in

the second case OSHA checks, approves, and monitors the application of State plans, which have been prepared and adopted by individual states.

- b) Workers employed in state and local government agencies benefit from the OSH Act if they work in a state where an OSHA-approved specific state plan is in force.
- c) Federal agency workers are protected by OSHA, which is entitled to inspect workplaces but not to fine the agencies in the event of discovering any irregularities.
- d) Self-employed workers, immediate family members of farm employers, and workers operating in sectors subject to control of other federal agencies (e.g., the Coast Guard and the Department of Energy) are excluded from OSHA coverage.

There are currently 22 state plans covering both private sector and state and local government workers; in addition, there are 6 state plans covering only state and local government workers. State plans must provide at least the same protection for workers as the Federal OSHA programs. Furthermore, state plans receive financial contributions from OSHA for up to 50% of their costs.

Structure of Governance

OSHA is a regulatory agency of the US Department of Labor and it is administered by the Assistant Secretary of Labor for Occupational Safety and Health. The Assistant Secretary answers to the Secretary of Labor, who is a member of the cabinet of the President of the United States. The Assistant Secretary is the OSHA’s executive officer and performs his or her duties with the support of the Principal Deputy Assistant Secretary and another Deputy Assistant Secretary. The Deputies coordinate and supervise OSHA’s eight Directorates and ten Regional Offices; these offices are located in Boston, New York, Philadelphia, Atlanta, Chicago, Dallas, Kansas City, Denver, San Francisco, and Seattle.

According to the OSH Act of 1970, further bodies are entrusted with advisory functions.

The National Advisory Committee on Occupational Safety and Health advises, consults with, and makes recommendations to the Secretary of Labor (and the Secretary of Health and Human Services) with reference to programs and policies for the prevention of accidents in the workplace and work-related diseases. The National Advisory Committee is appointed by the Secretary of Labor and comprises 12 members, who must possess experience and expertise on occupational safety and health and represent different stakeholders: employers, workers, occupational safety and health professionals, and the public. The members serve 2-year terms.

The Secretary of Labor may also appoint short-term advisory committees to assist him or her in setting the standards. Such committees have a maximum of 15 members, including one member recommended by the Secretary of Health and Human Services. The other members represent employers and workers, in equal number, and other health and safety agencies. All the members must be highly qualified in the areas the standards cover and must not have any direct economic interest in the proposed standards.

Activities/Major Accomplishments/Contributions

Setting standards for the prevention of workplace injuries and work-related illnesses is OSHA's core activity. In addition, OSHA has the duty of conducting inspections to verify corporate compliance with the regulations in force. In order to ensure that workplaces are free of severe hazards, OSHA also provides training, outreach, education, and assistance to employers, workers, and professionals in occupational safety and health. All these activities are described below.

Standard-Setting

The OSH Act of 1970 gave OSHA broad authority in issuing workplace safety and health standards (Robinson et al. 2010). In the first 2 years

after the creation of OSHA, the Secretary of Labor had the power to adopt "interim standards," usually through the implementation of preexisting consensus standards. On 29 April 1973, this option ceased to exist: since then, OSHA has exercised its regulatory function by establishing "permanent standards" and "emergency standards."

A "permanent standard" can be either a newly proposed standard or an amended one. In both cases, OSHA may receive recommendations from the National Institute for Occupational Safety and Health (NIOSH), established by the OSH Act of 1970 within the Department of Health and Human Services. NIOSH performs research and experimental programs for the prevention of work-related injuries, illnesses, disability, and death. Based on the results of such activities, NIOSH is entitled to make scientifically based recommendations to OSHA for the preparation and issue of a new standard or the improvement of an existing one (Levy et al. 2018). However, the standard-setting process also involves other interested parties, such as state and local governments, associations representing employers and workers as well as other nationally recognized standard-setters. In particular, the law gives small businesses the right to express their views during the standard-setting process.

The process starts with preliminary rulemaking activities, which enable OSHA to understand the need for a new or revised standard, conduct research, and develop feasibility analyses. If OSHA decides to proceed, it draws up a draft rule following the recommendations and opinions of its advisory committees: the National Advisory Committee on Occupational Safety and Health, the Advisory Committee on Construction Safety and Health, the Maritime Advisory Committee for Occupational Safety and Health, and other short-term committees specifically appointed by the Secretary of Labor. Then, OSHA publishes the draft standard, which is subject to a public consultation for a minimum period of 2 months. Moreover, OSHA holds public hearings to discuss the content of the draft standard with qualified

counterparts and other interested stakeholders. When the revision of the draft rule has been completed, the final standard is officially issued and becomes effective. However, the entire standard-setting process is so complex that it can require several years.

The procedure can be significantly shortened and simplified when there is the urgent need to protect workers from grave and imminent dangers. In such circumstances, the Secretary of Labor has the authority to adopt an “emergency standard.” This is a temporary standard, whose creation bypasses the formalities designed for permanent standards. After issuing an emergency standard, the Secretary of Labor must immediately activate the procedure to transform it into a permanent standard; the transition must be concluded within 6 months. Throughout its history, OSHA has adopted only nine emergency standards, but five of them were rescinded.

OSHA’s standards must be implemented by private and public sector employers, according to OSHA’s coverage, and respected by all workers. In particular, OSHA’s standards identify and require employers to adopt procedures and tools through which hazards to safety and health in the workplace can be reduced or even eliminated. According to OSHA’s standards, the first step in occupational safety and health risk management must be the adoption of collective measures (such as establishment of fall protection and ventilation systems). Where necessary, these must be integrated (or replaced) by the distribution of personal protective equipment (such as safety footwear, helmets, masks, and respirators) to all the workers exposed to the risk. The law also states that the cost of the equipment must be borne entirely by the employer.

Many processes developed in construction, maritime, agriculture, and general industry are subject to specific standards. Evidently, measures vary according to the industry.

Where a standard does not exist, employers are still obliged by the OSH Act to respect a “General Duty Clause,” which requires the provision of a

workplace free from recognized hazards that could cause death or serious physical harm to workers. As the normal procedure to release a permanent standard is very slow, the General Duty Clause has special significance.

Inspections, Citations, and Fines

OSHA is also responsible for the enforcement of occupational safety and health regulations and standards. In this regard, OSHA has the power and duty to conduct scheduled and spot inspections (Ko et al. 2010; Jung and Makowsky 2014).

If OSHA suspects that an employer is breaching the law and has failed to implement standards, it has the authority to perform an investigation without advance notice. Inspections are performed in the case of imminent danger, fatalities, and hospitalizations. Inspections can also be requested by workers who are seriously concerned about the existence of hazards in their workplace: in such an event, they have the right to file a complaint with the nearest OSHA office. In this regard, it is important to underline that OSHA’s Whistleblower Program protects any worker who has filed a complaint and requested an inspection, prohibiting any type of retaliation (such as dismissal, demotion, or denying benefits or promotion) by the employer.

When OSHA decides or accepts to conduct on-site inspections, it sends trained compliance officers from its regional offices to visit the premises and interview both the employer and the employees. If the compliance officers find violations of occupational safety and health legislation and standards, OSHA can sanction the employer by issuing citations and fines. Citations may specify corrective actions to be made and a reasonable time in which to resolve the problem. OSHA can also order follow-up inspections to check on progress made.

However, both employers and workers can appeal to the Occupational Safety and Health Review Commission (OSHRC) to contest OSHA’s decisions. OSHRC is an independent federal agency, separate from OSHA and the Department of Labor. It is appointed by the

President of the United States and it is composed of three qualified members with a 6-year mandate. OSHRC acts as an administrative court: it receives evidence, holds hearings, and decides about citations and fines issued by OSHA and contested by an interested party. An employer may challenge any alleged violation discovered by OSHA inspectors; in addition, he or she may contest the corrective measures imposed by the citation and the date by which they must be implemented. Finally, the employer may also contest the amount of the fine to be paid. By contrast, workers (or their representatives) may only challenge the time allowed to the employer to undertake the corrective actions.

Cooperative Programs

Several programs encourage cooperation between OSHA and its stakeholders, including employers, employees, trade associations, unions, government agencies, and occupational safety and health professionals. These initiatives help employers build a safer and more healthful workplace, in the interest of workers. There are also obvious advantages for the employers themselves, because effective processes of risk prevention result in fewer accidents, lower worker compensation insurance premiums, lower rates of worker absence and turnover, and better reputation. Furthermore, companies that complete certain programs (Leeth 2012) appropriately may be temporally exempted from OSHA's periodic inspections.

The *Alliance Program* allows OSHA and its stakeholders to share information and work together in order to develop new practices and tools for the effective management of occupational hazards.

The *OSHA Challenge* program promotes cooperation between employer and employees, on the one hand, and OSHA-approved volunteer Challenge Administrators, on the other. Challenge Administrators support business operators across a three-stage program, which should lead to the implementation of a safety and health management system in line with the OSHA voluntary

Guidelines of 1989. After the successful completion of each stage, OSHA Challenge participants are awarded a letter of recognition from OSHA, which can boost their reputation.

Another remarkable initiative is the *Safety and Health Achievement Recognition Program* (SHARP), which focuses on small businesses. SHARP status is awarded to small employers who adopt exemplary procedures to manage occupational risks: this not only improves the firm's reputation, but also ensures exemption from OSHA programmed inspections for up to 2 years.

Major corporations, firms involved in large construction projects, and government agencies can participate in the *OSHA Strategic Partnership Program* (OSPP), which encourages cooperation at multiregional and national level as well as at local level.

Firms and federal agencies that have maintained injury and illness rates below the national averages of their industry can apply for OSHA's *Voluntary Protection Programs* (VPP). To enter a VPP, firms and federal agencies must pass rigorous on-site assessment. VPP participants are then reevaluated every 3 to 5 years to maintain their status, which foresees exemption from OSHA's programmed inspections.

Introduction/Definition

The importance of our oceans to the proper functioning of our planet and the well-being of all

species, including humans, is immense. The ocean covers more than 70% of the earth's surface, playing a key role in the regulation of global climate. It is the largest carbon sink, contributing as much as 83% to the global carbon cycle, and taking up around 23% of the total anthropogenic CO₂ emissions (Hauck et al., 2020; Heinze et al., 2015). The ocean absorbs and distributes solar heat and precipitation through its currents and evaporation processes, supporting the earth's temperature and weather patterns (Manabe, 1969). In addition, the ocean provides habitat for a large abundance and biodiversity of species, forming roughly 12 different types of ecosystems, such as coral reefs, mangroves, and seagrasses that sustain key ecosystem services (Cisneros 2016; Barbier, 2017). For example, more than half of the world's oxygen originates from the ocean through the photosynthetic activity of marine plants and bacteria. Ecosystems such as mangroves largely contribute to carbon sequestration, and shoreline stabilization and erosion control (Barbier, 2017). That is, the dense roots of mangrove forests slow down water flows and encourage the deposition of sediments which reduces erosion of coastlines. Besides these, oceans provide several other ecosystem services that support human livelihoods, in terms of subsistence, economic, and cultural values. More than 3 billion people depend on marine resources for subsistence. Artisanal and small-scale commercial fisheries are especially important in developing countries, mainly contributing to food security, economic growth, and job creation (Barbier, 2017; Cisneros-Montemayor et al., 2016). Recreation and tourism, transportation and spiritual/cultural well-being are other services provided by marine ecosystems. Many coastal communities, especially indigenous peoples and small rural communities have expressed the ensemble of their identity to be intrinsically connected to the ocean (Cisneros-Montemayor et al., 2016).

Yet, overexploitation, habitat deterioration, and poor management of marine resources originating from human activities are considerably impacting marine ecosystems. Climate change and related increases in carbon dioxide into the atmosphere are challenging the ocean's capacity

to absorb carbon, leading to ocean acidification (Doney et al., 2020; Fabry et al., 2006). Climate change, as well as overfishing and pollution (e.g., industrial activity byproducts, agricultural run-off, sewage) are also responsible for losses in species abundances and biodiversity and changes in species distribution throughout the globe (Coll et al., 2008; Hatje et al., 2018; Noyes et al., 2009; Pecl et al., 2017). Ocean noise originating from activities such as shipping, drilling and tourism is also known to affect sensitive species like cetaceans (Weilgart, 2007). These anthropogenic impacts influence long-term development and sustainability. As a result, to reap long-term benefits, it is critical to find a solid and comprehensive solution for ocean sustainability (Lubchenco et al., 2016). Here we discuss long-term ocean sustainability.

The Sea and the Sustainable Development Goals of the United Nations

Since the United Nations Member States approved the Agenda for Sustainable Development in September 2015, there has been a need to better understand the interconnections and relationships among the 17 sustainable development goals defined in the agenda (SDGs) (Le Blanc et al., 2017). The SDGs are the blueprint to achieve a better and more sustainable future for all, they are:

- Goal 1: "No Poverty".
- Goal 2: "Zero Hunger".
- Goal 3: "Good Health and Well-Being".
- Goal 4: "Quality Education".
- Goal 5: "Gender Equality".
- Goal 6: "Clean Water and Sanitation".
- Goal 7: "Affordable and Clean Energy".
- Goal 8: "Decent Work and Economic Growth".
- Goal 9: "Industry, Innovation, and Infrastructure".
- Goal 10: "Reduced Inequalities".
- Goal 11: "Sustainable Cities and Communities".
- Goal 12: "Responsible Consumption and Production".

- Goal 13: “Climate Action”.
- Goal 14: “Life Below Water”.
- Goal 15: “Life on Land”.
- Goal 16: “Peace, Justice and Strong Institutions”.
- Goal 17: “Partnerships”.

The health of the ocean, particularly regarding its associated resources and human well-being, is being more recognized as inextricably interwoven. The ocean is crucial for long-term development since it covers more than two-thirds of the globe’s surface. Daily, more than 3.3 billion people depend on the ocean. Wild-caught and farmed seafood provide nearly 20% of the average per capita animal protein intake in countries such as Bangladesh, Cambodia, the Gambia, Ghana, Indonesia, Sierra Leone, Sri Lanka, and several small island developing states. Ocean foods also provide essential nutrients such as omega-3 fatty acids, vitamins, and other micronutrients such as calcium, iron, and zinc. In 2018, mariculture and coastal aquaculture produced 30.8 million tonnes of aquatic organisms, most of which were mollusks (FAO, 2020). By providing resilience, sustaining, and improving livelihoods, and promoting food security and poverty reduction and eradication, these contribute to SDGs 1 (No Poverty), 2 (Zero Hunger), 3 (Good Health and Well-Being), 8 (Decent Work and Economic Growth), and 14 (Life below water).

Furthermore, the oceans are the primary driver of global temperature, a significant sink for greenhouse gases, and a source of oxygen while supporting huge and diverse biodiversity. This activity contributes to the achievement of SDG 13 in part (Climate action). The accessibility to the ocean and the associated nearshore resources are vital components of ocean literacy. Ocean literacy is defined as an understanding of the ocean and our relationship with it (Santoro et al., 2017). Understanding the fundamental concepts necessary for sound decision-making in ocean sustainability and human health is vital. This factor will impact the human populations’ preparedness and resilience. To reach SDG 4 (Quality education), a sustainable blue economy that supports and promotes ocean literacy might be implemented (von Schuckmann et al., 2020). A sustainable blue

economy is the use of ocean resources for economic growth, improved livelihoods, and jobs while preserving the health of the ocean and the ecosystem (Phelan et al., 2020).

Frameworks for Ocean-Based Sustainability

Ocean sustainability embodies the approach employed to manage our oceans and the benefits they provide. A sustainability driver is any natural or manufactured force that causes a change in an ecosystem, either directly or indirectly. Negative environmental and social consequences must be minimized, while positive social and environmental advantages must be encouraged, all while ensuring profits for industries and governments. Sustainability management evaluates production processes and supports activities like planning and control, human resources, finance, and organization to achieve this motive. Ocean sustainability incorporates the approach required to manage our ocean and the services it provides. To realize the full potential of the ocean economy, it is relevant to effectively manage the ocean, use its resources sensibly, and reduce detrimental environmental impacts. Human pressure on marine ecosystems will only increase unless governments take sustainable measures to protect the ocean.

Due to the diverse uses of marine ecosystem resources, sustainable ocean development requires a comprehensive plan that considers social, cultural, economic, and governance elements, as well as environmental ones (Neumann et al., 2017; Visbeck et al., 2014). The Circles of Coastal Sustainability (CCS) framework incorporates and expands on Circles of Sustainability (James, 2014), a method for assessing ecological, economic, political, and cultural domains to understand complexity across multiple dimensions with social and environmentally sustainable outcomes in mind. Some frameworks go beyond checking environmental quality to identify the causes and consequences of environmental degradation linked to socioeconomic factors, thus connecting scientific findings with “real-world” issues and providing a more valuable and informed scientific base for resource management decisions. The Drivers

Pressures State Impact Response (DPSIR) and the Systems Approach Framework (SAF) (Elliott et al., 2017; Gari et al., 2014; Newton & Elliott, 2016) are two examples of frameworks that encompass a wide variety of sizes, methodologies, and timeframes. Despite using comparable frameworks in assessment methods such as the World Ocean Assessment to include both natural and social components of ecosystems, finding a balance between the two still is difficult; social variables are often disregarded in the assessment process.

A comprehensive coastal sustainability framework should encompass international policy goals such as the SDGs. It should improve coastal ecosystem sustainability and management by promoting the development of a framework that is able to assess the success of large-scale interventions and responses. Besides the SDGs, the Sendai Framework for Disaster Risk Reduction, Paris Agreement, and Aichi biodiversity goals are other international policies tackling societal challenges such as climate change, severe events, poverty, and marine systems. Another example is the Ocean Health Index (OHI) that classifies ocean health based on ten widely agreed-upon societal goals (Alcamo & Bennett, 2003). Its goal is to serve as a critical reference point for future progress and inspire a comprehensive ocean strategy, considering both detrimental and beneficial effects. Consequently, data input quality has a considerable influence on OHI outcomes. The OHI provides helpful visual assistance, but the underlying statistics are complex and based on assumptions that are easily changed by data quality. The framework addresses how the degradation of coastal ecosystem services may affect human well-being and how power relations, overlaps, and conflicts may influence management and contribute (or not) to the long-term sustainability of ecosystems and human well-being.

Innovation and Solutions Based on the Ocean

Developing a sustainable ocean economy may be difficult because of the ocean's immensity and importance to the global economy and people's lives. The ocean is more than just a source of

revenue for billions of people. Humans are intrinsically connected to the ocean spiritually, culturally, and recreationally. Small-scale solutions and high-level initiatives may contribute to developing a long-term ocean economy based on the three Ps of adequate protection, long-term production, and fair prosperity. Human activities must be controlled wisely to conserve biodiversity, vital ecosystems, and the cultural and spiritual importance of the ocean.

Some preventive measures include improving water conservation by reducing our water usage in homes, farms, and businesses, reducing the incorporation of polluting substances (trash) into the seas, and preventing plastics from seeping into the ocean.

Proper disposal of plastic waste, recycling techniques, and eliminating unnecessary plastics is a solution. Making companies responsible for their plastic usage by applying the Extended Producer Responsibility (EPR) principle is an excellent strategy to prevent ocean plastic pollution. The EPR is a policy approach under which producers are given a significant financial or physical responsibility for the treatment or disposal of post-consumer products. Among the advancements in emerging countries are investments in recycling technology, infrastructure, and garbage collection systems. Another solution is the use of precision farming, this is referred to as an approach to farm management that uses information technology (IT) to ensure that crops and soil receive exactly what they need for optimum productivity. This is to ensure the protection and sustainability of the environment and also help to reduce nutrient and sediment runoff into the ocean.

Management of Ocean Cost and Finance

In running ocean-related activities, there are various costs to be incurred. The current financial cost of protecting our ocean is vast. Thus, a huge financial resource is needed for general biodiversity conservation. Apart from the fact that there is a funding gap, investing in ocean sustainability requires about half of the cost of the expenses needed for general biodiversity conservation (Johansen & Vestive, 2020; Sumaila et al., 2020).

The demand for and supply of financial resources for investment in ocean-related economic activities and governance is the subject of ocean finance. Ocean finance must be appropriate and directed toward sustainable use and control of the ocean and its resources to sustain the ocean economy. Generating, investing, aligning, and accounting for financial resources are important aspects of funding. Individuals, public and private organizations, governments, and other non-governmental/inter-governmental institutions can access and use financial instruments locally, nationally, and internationally (Sumaila et al., 2020).

Sensible and stable regulatory policies should be established to generate funding, and investment is required to manage the cost and finance. This issue may be accomplished by revising laws and enacting rules that enhance natural capital management and encourage and reward social business and new forms of capital (Morgan & Network, 2014; PEMSEA, 2015), therefore, leading to the creation of regulatory frameworks in the fishing industry that protect tenure and provide rigorous enforcement mechanisms (Holmes et al., 2014; Thiele & Gerber, 2017) or policies that encourage technology transfer and incentivize renewable energy (Hemer et al., 2018).

Governments should also establish conditions that allow people to access credit, savings, micro insurance, and other services (Sumaila et al., 2020). Further, market-based benefits, like certification, can boost project investment opportunities by ensuring sustainability across the supply chain and introducing more transparent monitoring methods (Lubchenco et al., 2016). Increased openness and adequate national, regional, and global fishing data infrastructure should be established to improve knowledge sharing and facilitate both management and remediation. More thorough and consistent monitoring and reporting on finances for a sustainable ocean economy, particularly biodiversity financial flows, are required in both the public and private sectors (OECD, 2019). This provides expenditure that contributes to the conservation, sustainability, and restoration of biodiversity.

Individually and regionally, countries should invest in terms of data and analysis, while national and state organizations must be able to track

expenditures (Sumaila et al., 2020). There is a need to enhance human capacity for gathering, investing, and coordinating ocean financing in many developing maritime nations to produce the knowledge needed to attract investors into the ocean economy. Practical capacity training in ocean finance, insurance, and fiscal mechanisms is needed to promote investment in a sustainable ocean economy, particularly from multilateral organizations or bilateral aid (Sumaila et al., 2020).

Summary

The term “ocean sustainability” could be referred to as a term to manage the seas and the associated resources. The Sustainable Development Goals (SDGs) are a framework for achieving a better and more sustainable future for all people by increasing resilience, supporting, and strengthening livelihoods, fostering food security, and eradicating poverty. SDG 14 is to conserve and use oceans, seas, and marine resources for sustainable development while also guaranteeing human well-being and adequate ecological function. Developing a sustainable ocean economy may be challenging because of the ocean’s vastness and significance to the global economy and people’s lives. Small-scale solutions and high-level efforts might help build a long-term ocean economy based on proper conservation, long-term production, and equal wealth. Human activities should be managed carefully to protect biodiversity, critical ecosystems, and the ocean’s cultural and spiritual significance. The ocean affects all living creatures, which supports the earth’s temperature and weather patterns by transporting heat from the equator to the poles. Similarly, it plays an essential role in controlling CO₂ levels in the atmosphere by absorbing a part of anthropogenic carbon emissions. On the other hand, humans are having a detrimental influence on the ocean waters. The ocean environment is influenced by acidification, pollution, overfishing, irregular, unreported, unregulated fishing, drilling, ocean warming, and deterioration of ocean-sensitive habitats and ecosystems. These human influences affect long-term development. Consequently, it is essential to investigate a robust and

complete ocean sustainability solution to gain long-term advantages. To guarantee the long-term existence of future generations, the global ocean must be protected and managed. We must take intelligent actions to end hazardous pollutants and support the ocean's treasures to guarantee its long-term viability.

Description

The Organization for Economic Co-operation and Development (OECD) Guidelines for Multinational Enterprises are widely disseminated, highly influential guidelines for the operation and regulation of these major global actors. To understand the nature and goals of the Guidelines, it is helpful to understand the origins of the OECD itself. As a post-World War II institution, the OECD emerged from the Marshall Plan, initially in the form of the European Recovery Program which in turn evolved into the Organization for European Economic Co-operation. After addressing its initial mandate, the OECD turned to social and economic goals.

Through its social and economic goals, the OECD turned its attention to the increase in multinational enterprises (MNE). Recognizing the increasingly important role these MNEs played in the economic and political spheres led the OECD to develop the OECD Guidelines for Multinational Enterprises (Guidelines). The Guidelines are composed of 11 principles which deal with sustainability issues (Sheehy and Farneti 2021) such as human rights and the environment among other matters.

The Guidelines are recognized as soft law – that is, law that voluntarily adopted. While some parties believe that such laws are not meaningful because they lack enforceability, others believe that they provide guidance on behavior which over time become the accepted behavioral norms. As the Guidelines become more widely accepted and endorsed, there is potential for them to come to be recognized as hard law enforceable by courts.

Background and Early Development of the OECD

The OECD, like the United Nations, was a post-World War II institution. In 1947, the then US Secretary of State, George Marshall, stated that the international relations policy of the USA should focus on building a world order that will facilitate the growth of “free institutions” (Wolfe 2008). Focusing on the role of America in the war

reconstruction efforts, the Marshall Plan was created – a plan subsequently hailed as “history’s most successful structural adjustment program” (DeLong and Eichengreen 1993) – saving European countries from financial collapse by providing USD \$13 billion. The plan provided for the period of 1948–1951, allowing recovery by raising growth in participating countries’ industrial output at varying degrees from Turkey’s 75% to Austria’s 269% (Eichengreen and Uzan 1992).

There was a realization among state actors that “economic cooperation can serve political purposes” (Wolfe 2008) and this was realized through the Marshall Plan. By 1948, the Committee of European Economic Cooperation was created to manage the recovery plans of Europe as spearheaded by Britain and France and present a European Recovery Program to justify the expenses of the USA (OECD n.d.-c “Historical”). The Organization for European Economic Co-operation (OEEC) (OECD 2009) was then established in Paris, France, with 18 initial state actor participants, namely, Austria, Belgium, Denmark, France, Greece, Iceland, Ireland, Italy, Luxembourg, the Netherlands, Norway, Portugal, Sweden, Switzerland, Turkey, the UK, and Western Germany.

By 1950, the OEEC was focused on creating a single European Market, giving rise to the current situation today of the European Union. By 1960, a more permanent convention than the OEEC primarily focused on the Marshall Plan, to address the interests of the initial 20 founder countries (OECD n.d.-a “About”) (by then 38) to promote the following OECD (n.d.-b) “Convention”:

- (a) To achieve the highest sustainable economic growth and employment and a rising standard of living in member countries, while maintaining financial stability
- (b) To contribute to sound economic expansion in member as well as nonmember countries in the process of economic development
- (c) To contribute to the expansion of world trade on a multilateral, nondiscriminatory basis in accordance with international obligations

The OEEC was reorganized as the OECD and expanded its focus beyond economic development to include social welfare and environmental sustainability. Founded in 1961 with its headquarters in Paris, France, a situation which prevails up to the present day, the OECD’s purpose has been woven into the network of member states, making it a key, if often unnoticed, player in transnational governance (Mahon and McBride 2009). It was credited for Europe’s rejection of communism – without any significant publicity. The OECD was a promoter of Keynesian Economics as implemented through the Marshall Plan, and it was the success of the later in stimulating the economies of member countries during the Cold War (Lingard and Sellar 2016) that kept Western Europe free.

The OECD does not directly shape policy like other multinational and international organizations like the United Nations by providing conventions, model laws, grants nor state support, or loans like the International Monetary Fund or the World Bank. Rather, the OECD acts more like a policy research and resource center which promotes, monitors, and tests the policies of its member states through various country desks, ultimately reaching the OECD’s Secretariat and Subject Matter Departments. While published research provides recommendations rather than mandates, they may present a call to action, such as in establishing tax norms through the OECD Model Convention (Ault 2008).

OECD and Sustainability

In the period between 1968 and 1974, the research on the drivers of growth was a topic of debate in the OECD between the secretariat team and the committee on science and technology policy. The debate led to the consideration of the natural environment (Schmelzer 2012). Governments, they urged, are faced with the realization of competing interests in their pursuit of the path to development. On one hand, while conservation of natural resources is most desirable, they argued on the other that it should not come at the expense of hungry mouths to feed or rather foregoing

economic progress (Tracey and Anne 2008; Sheehy 2019). This realization led to the creation of the OECD Environment Committee – a major forum for member states to address dialogue environmental issues (OECD n.d.-d “Celebrating”).

This forum provided the opportunity for the 1971 creation of the “Polluter Pay Principle” – a principle which requires the creator of the pollution to bear the cost of any measure determined by the government regulator as a deterrent from inflicting more damage to the environment (Tracey and Anne 2008; Sheehy 2019). In the absence of this principle, the government is tasked with paying for cleanup of pollution created by business, as, for example, in instances of oil spills.

In 1987, the OECD was also part of the Brundtland Commission which defined sustainability as “meeting the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland 1987). It encouraged the use of the legal framework through the passage of environmental laws, with consequences ranging from imposition of penalties to requirement of categorization of activities and collecting fees (OECD 2008).

Guidelines for Multinational Enterprises

The Guidelines contain 11 principles. After a general introductory principle, the first principle provides guidance on their interpretation, the remaining ten deal with distinct areas of MNE activity. The following quotes the basic exposition of each directly from the principles:

- I. General Policies Enterprises “should take fully into account established policies in the countries in which they operate, and consider the views of other stakeholders.”
- II. Disclosure Enterprises “should ensure that timely and accurate information is disclosed on all material matters regarding their activities, structure, financial situation, performance, ownership, and governance. This information should be disclosed for the enterprise as a whole, and, where appropriate, along business lines or geographic areas. Disclosure policies of enterprises should be tailored to the nature, size, and location of the enterprise, with due regard taken of costs, business confidentiality, and other competitive concerns.”
- III. Human Rights “States have the duty to protect human rights. Enterprises should, within the framework of internationally recognized human rights, the international human rights obligations of the countries in which they operate as well as relevant domestic laws and regulations.”
- IV. Employment and Industrial Relations “Enterprises should, within the framework of applicable law, regulations and prevailing labour relations and employment practices and applicable international labour standards.”
- V. Environment “Enterprises should, within the framework of laws, regulations, and administrative practices in the countries in which they operate, and in consideration of relevant international agreements, principles, objectives, and standards, take due account of the need to protect the environment, public health, and safety, and generally to conduct their activities in a manner contributing to the wider goal of sustainable development.”
- VI. Combating Bribery, Bribe Solicitation, and Extortion “Enterprises should not, directly or indirectly, offer, promise, give, or demand a bribe or other undue advantage to obtain or retain business or other improper advantage. Enterprises should also resist the solicitation of bribes and extortion.”
- VII. Consumer Interests “When dealing with consumers, enterprises should act in accordance with fair business, marketing, and advertising practices and should take all reasonable steps to ensure the quality and reliability of the goods and services that they provide.”
- VIII. Science and Technology “Enterprises should endeavor to ensure that their

activities are compatible with the science and technology (S&T) policies and plans of the countries in which they operate and as appropriate contribute to the development of local and national innovative capacity.”

- IX. Competition “Enterprises should carry out their activities in a manner consistent with all applicable
- X. Taxation “It is important that enterprises contribute to the public finances of host countries by making timely payment of their tax liabilities. In particular, enterprises should comply with both the letter and spirit of the tax laws and regulations of the countries in which they operate.”

Analysis

The Guidelines offer significant support for sustainability. As the leading policy statement globally for MNE behavior, they command attention and respect by all actors. Further, by containing principles on issues identified in the Sustainable Development Goals, they contribute to coherent global norms on certain sustainability issues. They provide principles for compliance with national laws and so promote rule of law. They provide principles for human rights and by doing so promote human rights. Finally, they provide principles for environment through which they promote environmental protection.

Other scholars have contributed to the analysis. For example, Chatterjee emphasized the need to have special provisions addressing the needs of developing countries and to help them develop their infrastructures, as the current Guidelines assume that they may be applied to both developed and developing countries. Given their global reach, they do; however, adding nuance would benefit both the Guidelines as well as the countries beyond the OECD.

A significant concern among scholars and stakeholders is the soft law nature of the Guidelines. For example, Davarnejad notes the considerable variations of interpretations and

applications of the Guidelines, their implementation, and their compliance, which he argues is the result of their unenforceability. Being a soft law, however, does not mean that the Guidelines would not achieve their purpose: Davarnejad admits that while the flexibility of the Guidelines tends to diminish their impact, the soft law character allows the participants to try their own approaches which could well eventually achieve the Guidelines’ purpose.

Taking the argument further, Plaine provided three reasons why the Guidelines, despite their voluntary nature, must not be ignored: (1) for good public and governmental relations; (2) they are indicative of the future of international law; and (3) the advantage to business of using a recognized standard of conduct for both MNEs and governments. Given the history and development of the Guidelines and the efforts and participation of various stakeholders including members of the business community, the consensus built around what constitutes good corporate behavior would be hard to violate. Similarly, this consensus may well translate into actual compliance which in turn could become a business norm, a law merchant, simply awaiting recognition through the courts.

Finally, having a standard of conduct enhances the obligation of states to accord fair treatment to MNEs. Thus, the practice of preferencing local businesses that may be inefficient or corruptly supporting local governments is put to the test by the recognition of MNEs and fairness in treatment as a principle.

Further, there has been exploration of the potential impact of the Guidelines in promoting and protecting human rights and related proposals for reform. For example, Černič argued that considering the evidence of human rights violations by or involving corporations, the Guidelines must be tested not only against their primary objective related to investments, rather they need to be evaluated in terms of their potential as mechanisms to ensure that MNEs respect human rights. Černič offered four proposals to strengthen the Guidelines in addressing human rights violations committed by MNEs: (1) translate complaints mechanism under the Guidelines into quasi-legal

employment tribunal to deal with complaints; (2) ensure MNEs to actively participate in the complaint process; (3) give national contact points a better role in promoting the content of the Guidelines, and finally ensuring transparency and accessibility; and (4) make national contact points informed, authoritative, and command confidence of all participants. These proposals, however, would necessitate reform of the Guidelines.

As MNEs continue to increase their influence over government institutions in the domestic level, it is believed to be no more than a matter of time before they have significant influence on the international level as well. Revising the Guidelines in the future must take this likelihood into consideration to ensure they do not impede states from fulfilling their domestic and international obligations. One way for this to occur would be if Principle II were made binding on all MNEs.

Summary

The OECD Guidelines for Multinational Enterprises represent the outcome of over half a century of development and experience with these entities. Although originating in post-World War II Europe, they have become de facto global soft law. The Guidelines are important to sustainability in part because of their promotion of collaboration with governments and so upholding the rule of law, human rights, and environment.

[Entrepreneurship Outlook](#); [OECD Recommendation](#); [SMEs growth](#); [SMEs innovation](#)

Definition

The Organisation for Economic Co-operation and Development (OECD) represents a forum where governments address social, economic, and environmental challenges at a global level. Acting as a macro institutional setting, this *milieu* allows governments to compare policy experiences, share best practices, and find global solutions to tackle critical changes through the coordination of national and international political agendas. In this context, since the early 1940s SMEs have been considered by the OECD as a driver to advance trade and industrialization in developed nations (OECD 1997 and 2004). A specific center has been set up to help local, regional, and national governments to enhance entrepreneurs' and SMEs' potential as well as inclusive and sustainable growth. The work of the OECD and other international institutions is fundamental to strengthen SMEs' contribution to economic and social cohesion, as well as through the role played by women and young entrepreneurs.

OECD guidelines yield a comparative analysis of regulative frameworks and policies to improve SMEs' contributions and provide insights on the challenges and opportunities of entrepreneurs and SMEs, as well as an updated overview of each country profile relative to SMEs' performance.

Within the broader OECD strategy on SMEs, the *Recommendation on SME and Entrepreneurship Policy* was adopted in June 2022 – and launched on the occasion of a special event, the “UN Micro-, Small and Medium-sized

Enterprises Day” that took place on June 27 – on the proposal of the Committee on SMEs and Entrepreneurship with the aim to provide a holistic framework to develop effective SME and entrepreneurship policies and foster their contribution to inclusive and sustainable growth.

Introduction

The “micro, small and medium-sized enterprises” have been defined as enterprises that hire fewer than 250 employees and have an annual turnover not exceeding 50 million euro and/or a total on the annual balance sheet of 43 million euro (Extract of Article 2 of the Annex of Recommendation 2003/361/EC – European Commission: Enterprise and Industry, Small Medium Sized Enterprises 2005). Beyond the general agreement on this definition within the European countries, SMEs are still defined differently throughout the world depending on the policy-maker focus. SMEs can be identified both through specific quantitative-based criteria (i.e., turnover, asset value, total employees, profit, balance sheet capital, financial provisions, and market share) and qualitative variables, such as the type of governance, ownership, the presence of managers, or the adoption of managerial systems (Etuk et al. 2014). However, although different definitions exist, there is a consensus on their fundamental role and contribution to economic growth, innovation, and job creation, as well as to social cohesion in both developed and emergent countries.

Moreover, both scholars and policy-makers agree on SMEs' contribution in boosting innovation, supporting more inclusive growth, and facing the major challenges of normal and exceptional times. This contribution has become urgent particularly in the aftermath of the Covid-19 pandemic crisis that called on governments to support SMEs' resilience and revitalization focusing on digital and green evolution.

Indeed, within the OECD countries, SMEs represent a large portion of total employment growth, as well as the Gross Domestic Product. Despite the crises, SMEs are among the main drivers of development and largely contribute to

preserving the identity and social cohesion of local communities in urban and rural areas (Jenkins 2006; Morsing and Perrini 2009).

However, as mentioned, SMEs represent a “universe” that encompasses a variety of types whose performance differs greatly across sectors and regional areas (IFC 2006). Due to the reduced endowment of resources (financial and human resources), they operate in sectors characterized by low entry barriers (i.e., in terms of capital and assets for funding, patents, etc.), such as the service sector, while there are comparatively fewer SMEs in manufacturing service that require a larger scale of production. Their reduced size and simplified structure give SMEs a high level of flexibility – their flat management structures call for the entrepreneurs and employees to fulfill multiple roles – which makes them capable of rapidly responding to changes and adapting to market needs promptly, unlike large businesses. Moreover, among the features that mirror the specific nature of SMEs are the governance system, characterized by the overlapping of ownership and control (due to the family-business nature) and the direct involvement of the founder and his/her family in managing the business, the ease of the organizational structure, which favors personal relationships with the stakeholders, and the embeddedness in the community and the local area (Del Baldo 2012; Looser and Wehrmeyer 2015). Notably, this last factor assumes particular importance in driving SMEs to actively contribute to the social capital and development of the local context in which they are embedded (Ringov and Zollo 2007).

Accordingly, SMEs play a key role in achieving the goals set by the 2030 Agenda (UN 2015; SNV/WBCSD 2007), the holistic proposal for action on social, economic, and environmental issues. The OECD pays close attention to entrepreneurship and SMEs and contributes to the operationalization of the Agenda by: (1) refining policies and how they work together; (2) generating resources for sustainable development; (3) fighting for everyone’s well-being; (4) guaranteeing the planet’s sustainability; (5) capitalizing on the power of partnerships;

(6) fortifying data availability and capacity; and (7) enabling follow-up and review.

Key Issues

The OECD constantly monitors business dynamism, wage gaps, productivity growth, and export trends of business from all countries (OECD 2019a; UNCTAD 2001). Legal instruments of the OECD encompass: the OECD Bologna Charter on SME Policies (adopted as a Declaration *Enhancing the Competitiveness of SMEs in the Global Economy: Strategies and Policies* on June 15 2000); the OECD Istanbul Ministerial Declaration on Fostering the Growth of Innovative and Internationally Competitive SMEs; the OECD Declaration on Strengthening SMEs and Entrepreneurs for Productivity and Inclusive Growth; and the G20/OECD High-Level Principles on SME Financing. Moreover, The OECD’s SMEs and Entrepreneurship Outlook provides an exhaustive overview of business conditions and policy frameworks for entrepreneurs and SMEs (OECD 2019d). The series is useful to assess and improve the performance, design, and implementation of entrepreneurship policies and share knowledge among OECD partner economies and member countries. The guidelines are founded on a typical methodology, including a diagnostic questionnaire completed by national authorities, and are reviewed by the OECD Working Party on SMEs and Entrepreneurship (OECD 2008). For instance, the annual publication on SMEs’ finance trends and conditions (OECD 2019b, c and d) provides information on debt, equity, and asset-based finance for SMEs and entrepreneurship finance. In this vein, the report “Data Analytics in SMEs Trends and Policies” devotes specific attention on digital technologies as a lever of SMEs’ performance, productivity, and innovation, and provides in-depth analysis of the policy approaches to foster data-driven decision-making in SMEs.

Favorable institutional frameworks are required if SMEs want to succeed. Governments should assist SMEs by implementing inclusive reforms, creating empowering frameworks, and

relaxing the weight of regulatory measures. Currently, there are several open areas of work aimed at strengthening their role within the local socio-economic fabric (Whermyer et al. 2019) and offering best practices on how to generate more and better-quality jobs through successful policy implementation and local initiatives, as well as supporting inclusive entrepreneurship and entrepreneurship in higher education. In this vein, the OECD Recommendation (2022) provides a response to a long-standing demand by countries for frameworks and tools to improve the effectiveness of SME and entrepreneurship policies, ensuring coherence and synergy across varied policy areas and actors, and accounting for the diversity of the SME and entrepreneurship population. OECD goals include fostering SMEs' productivity and growth; enhancing SMEs' access to finance; improving SMEs' digitalization; and enhancing entrepreneurship.

The Recommendation encompasses a mix of targeted and horizontal policy dimensions that emphasize the SMEs' governance mechanisms and take into account the contingent factors affecting the institutional contexts in different countries (i.e., the juridical settings and stages of development). The three pillars covered by the recommendation are: (1) policy coordination and governance; (2) transition and resilience; and (3) accessing resources.

The first pillar aims to put in place cross-cutting and coherent approaches to SME and entrepreneurship policy design and implementation by: coordinating and aligning SME and entrepreneurship policy across government; ensuring that implications for SMEs and entrepreneurs are considered across the diverse policy areas; taking account of the diversity of SMEs and entrepreneurs throughout policy-making; and setting up mechanisms to assess the impacts of policies addressed to SME and entrepreneurship.

The second pillar aims to facilitate the transition and resilience of SMEs and entrepreneurs by: supporting the adoption of digital technologies and services; enabling SMEs' transition toward sustainable business models, green innovations, and circular economy strategies; fostering SMEs'

access to resources and sustainable finance; enhancing SMEs' participation in global value chains, trade facilitations, and finance; strengthening their access to services and networks; reducing entry/exit barriers and business succession and re-start; ensuring supportive regulatory environments for innovative scale-up ventures; encouraging under-represented groups to participate in entrepreneurship and facilitating the transition from informal to formal entrepreneurship; and promoting SMEs' responsible business conduct and embeddedness in their local communities.

The third pillar aims to enhance SMEs' access to resources by: providing adequate incentives for SMEs and entrepreneurs to innovate (i.e., robust inclusive innovation ecosystems, local networks and infrastructures); enhancing their access to a range of financing instruments and strengthening financial skills; encouraging entrepreneurship education throughout society, and incentivizing SMEs to invest in skills (i.e., managerial skills, problem-solving, and digital skills); and strengthening entrepreneurial ecosystems at a local and regional level through networks between SMEs and large counterparts and linkages along supply chains.

Summary

As mentioned above, SMEs are regarded as the bedrock of industrialization in both the OECD and developing economies, where they generate the highest share of new employment. On the one hand, they are regarded as the chief suppliers of input to larger businesses as they provide customer-tailored services and products. On the other hand, they contribute to economic development through the creation of primary and intermediate products ranging from food, clothing, and healthcare to education, often grounded in innovations capable of triggering and dominating specialized markets (the so-called niches). SMEs are often led by entrepreneurs who are innovators and change agents and represent a vital factor in both economic development and social change. SMEs are often strongly embedded to their local areas and

depend on the community for a set of socio-economic resources, including intangible resources such as social capital, which, in turn, SMEs contribute to nurturing (OECD 2019). Accordingly, entrepreneurial success is measured by the enterprise's results, but even more so by the respect it gains from its community (Whermyer et al. 2019).

However, policy-makers and legislators, who usually target larger corporations, often overlook the needs of SMEs. SMEs usually do not benefit from tax incentives or business subsidies, and endure the large burden and cost of bureaucracy more than big enterprises, and most lack financial or human resources. Therefore, navigating from one crisis to another, many currently suffer from low productivity, curbing their role in boosting the socio-economic environment. "We need a fundamental rethinking of SME and entrepreneurship policies to improve business conditions and access to resources [...] and we need a renewed measurement agenda to understand how countries, regions and cities can capitalise on their many diverse small businesses as drivers for inclusive and sustainable growth" (A. Gurria, OECD General Secretary). Accordingly, behind the OECD Recommendation there is the assumption of the SMEs' heterogeneity and the need to strengthen policies and collective actions (OECD 2012). In this vein, the OECD's work is particularly relevant in that it drives government and other institutions' attention toward SMEs and their key role in promoting sustainable economies. In addition, it emphasizes the directions for policies that are necessary for the future of SMEs by leveraging on regulatory environments (including good governance and accountability in public administration and transparent tax regimes) conducive to entrepreneurship; promoting educational policies aimed at fostering an innovative entrepreneurial culture; and strengthening public-private partnership and social dialogue among institutional actors.

Definition

The Organization for Economic Co-operation and Development (**OECD**) Principles of Corporate Governance are the global standard of corporate governance (OECD n.d.). They build upon and consolidate prior research and development. Farrah (2003) defined corporate governance as the system by which companies are controlled and accountability structures and processes are imposed on those in control of companies. Sheehy and Diaz-Granados (2022) categorized two definitions of corporate governance, from narrow and broad scopes. A narrow scope is limited to the decision-making bodies of a company (Coffee 1986; La Porta et al. 2000; Shleifer and Vishny 1997) while a broad scope includes external stakeholders, such as policymakers, employees, and creditors (Hopt and Teubner 1984).

In their article, Sheehy et al. (2022) first described the history of corporate governance before turning into the history of the principles. Founded in the 1976 *Taming the Giant Corporation* (Nader et al. 2005), the concept of corporate governance subsequently developed in the 1990s in response to a series of business scandals and financial crises (Sheehy 2004). Having learned from these bitter experiences, in 1999 the OECD issued the first version of the OECD Principles of Corporate Governance (OECD 1999). It set the international benchmark for best practices for corporate governance internationally, irrespective of their membership in the OECD. The principles are, however, soft law and hence not legally binding (Bouchez 2007).

OECD Principles of Corporate Governance

Introduction

Since its issuance, the OECD has revised the principles twice, in 2004 and 2015. The next review and revision is ongoing, with an expected time completion of 2023. As of this date, the 2015 edition is the most recent version. Sheehy et al. (2022) summarized the six principles as follows:

- I. “Ensuring the Basis for an Effective Corporate Governance Framework” by requiring

the branches and institutions of government have clear roles in lawmaking, administration, and adjudication and a legal duty to follow the rule of law.

- II. “The Rights and Equitable Treatment of Shareholders and Key Ownership Functions.” This principle is focused on protecting independent and minority shareholders from exploitation by controlling shareholders.
- III. “Institutional Investors, Stock Markets, and Other Intermediaries.” This principle requires institutional investors, brokers, and other agents to act in the best interest of their beneficiaries.
- IV. “The Role of Stakeholders in Corporate Governance.” This principle requires protection for the interest of stakeholders on matters such as timely disclosure, minimum wage, and bankruptcy claim.
- V. “Disclosure and Transparency.” This principle requires companies to disclose material information to the public and providing equitable treatment to all shareholders.
- VI. “The Responsibilities of the Board of the Directors.” Finally, in its dealings with the directors, the principles require executive and nonexecutive directors and be accountable to shareholders and other interested stakeholders.

The OECD Principles of Corporate Governance is an answer to a global search for optimal corporate governance standards. Bebchuk and Hamdani (2009) counted over 100 studies documenting the search for optimal standards. Governments value good corporate governance, because it contributes to the attractiveness of local companies for foreign investment. Companies value optimal corporate governance, because it drives positive stock performance (Sheehy et al. 2022). While the principles are a widely accepted global model, they are not necessarily what determine successful corporate governance. As Subramanian (2015) explained in his article “Corporate Governance 2.0,” there is a lack of an accepted metric on what constitutes such success.

The principles are imperfect as one would expect with a broad standard in a dynamic environment, and this is a reason that the OECD continues to revise through each edition. This entry explains two aspects of the review and revision, namely family businesses and climate change governance.

Family Firms

While the principles need to be general to cover all OECD countries and broadly affected regions – all of which have their own corporate structure and ownership, it is crucial for the principles to particularly include guidelines for family businesses. Family businesses represent a majority of dominant industries in Asia (Fang et al. 2022), and Asia contributed 60% of global growth (IMF 2016; ADB 2017). Outside the USA, PwC (2017) projected that the largest markets in 2050 will be Asian – namely China, India, and Indonesia. This prediction remains unchanged despite the effects of COVID-19 (Galloway 2020). The Economist (2023a) recently observed that India and Indonesia are the world’s two fastest growing economies. Any corporate governance failures particularly in family businesses will thus have significant ripple effects in these markets.

Many family-owned companies are closely held and hence not subject to disclosure requirements. Asian family-owned companies in particular have highly concentrated ownership structure. This means boardroom decision-making is confined to family members and relatives. While these companies have the right to be self-regulating like any other type of closely held companies and have the incentive to perform better for their own financial self-interest, some of them might be less well-informed in decision-making. They may rely excessively on information of interest or drawn from preferred family sources, or they may prioritize family interests ahead of corporate interests. These are some of the many reasons that family businesses seldom survive the third generation (The Economist 2015; Fernández-Aráoz et al. 2015). Interestingly, family businesses last on average longer than

typical public companies (Baron and Lachenauer 2021). Further, given traditional institutional preferences, they will likely remain a significant feature of many large markets including Asia (The Economist 2015, 2023b).

Accordingly, the OECD may continue to reform its principles to include addressing the peculiarities of the corporate structure and ownership of family firms. The OECD Principles as soft law are particularly attractive to family firms as they do not impose changes to family firm structures and processes. It is left to the companies to choose whether and what to follow.

Climate Change

Over the last decade, there has been a greater advocacy for companies to contribute to climate change mitigation and to provide disclosure. They are expected to plan and disclose their climate change strategy. The draft revisions to the OECD Principles of Corporate Governance address what companies can do on this end; the draft considers climate change as a financially material risk, otherwise known as the “green swan” (Bolton et al. 2020).

Climate change poses a serious threat to the survival of humanity. It is also anticipated to be implicated in the next systemic financial crisis (Bolton et al. 2020). Addressing it through guidelines or soft law such as the OECD Principles of Corporate Governance obviously does not resolve the issue. The principles rely on corporate leaders’ discretion. Bebchuk and Tallarita (2020) argued that it is inadequate and substantially counterproductive to rely on such discretion to serve the broader interests of stakeholders. Corporate leaders, they argue, have not focused on addressing stakeholder interests and that it is unrealistic to expect such.

In the USA, a group of 22 law and finance professors questioned the value of the Securities and Exchange Commission’s climate disclosure rule proposal that was aimed at investor protection and public interest (Cunningham et al. 2022). Green disclosure alone is insufficient to increase firm value (Khan et al. 2021).

Coverage of climate change in the principles may pacify certain parties to the broader discussion on sustainability; it overemphasizes climate change as an issue of poor corporate governance when there are many competing agendas on the one hand (Sheehy and Farneti 2021), and many companies have little or no interest in environmental protection and mitigation aims on the other.

One-Tier Board

Maria Aluchna

Department of Management Theory, Warsaw School of Economics, Warsaw, Poland

Synonyms

[Board of directors](#); [Unitary board](#)

Definition

One-tier board, also known as the board of directors, the unitary board or the mono-system board, is the most important body in a corporation. It is

defined as a collectively working group of directors with the main function to provide oversight and control over the company as well as bring counsel and advise to its executives (Ruigrok et al., 2006; Larcker & Tayan, 2011). Members of the board (directors) are recruited from individuals with a particular knowledge, experience, and ethical stance in order to monitor the functioning of the company. The board is the strategic decision-making group and bears the ultimate responsibility for corporate performance and the control over executives (McNulty, 2014). The passive board characterized with inappropriate structure and insufficient level of independence and engagement is a significant drawback to efficient corporate governance (Gillespie & Zweig, 2010).

One-tier board is usually compared to the alternative model known as supervisory board or two-tier board which is also discussed in the Encyclopedia. The one-tier board functions in numerous countries worldwide including the USA, the UK, Australia, Canada, New Zealand, India, and Russia (Mallin, 2004). In several countries such as Italy, Spain and France the law allows the company to choose the board model between one-tier and two-tier model.

Functions and Duties

One-tier board is formed in the company to represent, formulate, and realize the interests of shareholders who provide funds necessary for the company's development. The role of the board is embedded in the ownership and organizational characteristics of the joint stock company. Specifically, the role of the board is conceptually placed in the principal-agent theory and the separation between decision management from decision control which takes place in large listed companies. This separation means that residual risk bearing is detached from decision management (Fama & Jensen, 1983a, b). In the language of the principal-agent theory such separation broadens the group of residual claimants and allows for risk sharing.

Conflicts between managers and shareholders impact the nature of managerial discretion in the

decision making and the managerial influence over the redistribution of profits. The board role is to address these challenges and mitigate conflicts. Specifically, board task is to protect the interests of shareholders, provide oversight over the top executives, and assure for long-term sustainable firm growth (Monks & Minow, 2004; Shleifer & Vishny, 1997). In public listed corporations directors who possess special knowledge, skills, and experience assure that the functioning of the company is targeted to increase the shareholder wealth. Hence, the task of board directors is to align the goals of managers with the interest of shareholders (Hambrick & Jackson, 2000). However, fulfilling the interests and expectations of shareholders, the board has to take into account the interests of the company as a whole. Directors are not only accountable to the company and its shareholders but have also responsibilities and duties to deal fairly with other constituencies including employees, creditors, customers, suppliers, and local communities.

Using the legal perspective board directors have a special relationship with shareholders and need to fulfill five main duties (Colley et al., 2003; Fisch, 2006; Monks & Minow, 2004; OECD/G20, 2015):

- The fiduciary duty which obliges directors to act to increase shareholder value in the long term while balancing shareholders expectations with the interest of the overall company and its stakeholders.
- The duty of loyalty and duty of fair dealing which refer to the supremacy of shareholder interests and put the interests of shareholders first over individual director's benefits. This requires to disclose any conflict of interest to refrain from taking advantage of the director position for the purpose of personal benefits.
- The duty of care which assumes that directors act carefully and are fully prepared once they participate in making decisions. Directors are expected to use their best knowledge and experience, perform during board meetings, and provide the best quality of monitoring, control, and counseling.

- The duty not to entrench is understood as the objective assessment of the company situation, openness, and readiness to undertake crucial decisions, particularly in the case of poor performance.
- The duty of supervision constitutes an integral part with the duty of fair dealing and refers to the effectiveness of directors when exercising oversight responsibilities. It requires the director to act in accordance with moral and ethical standards, fulfill the monitoring functions in a responsible way, and deliver the high quality of oversight. Directors are expected to be prepared before the board meetings, collect all necessary information, and be engaged and committed to the board work.

Bob Tricker identifies four main board functions including supervision, policy making, accountability, and strategy formulation (Tricker, 2012). On the practical level board directors (Adams et al., 2010; Larcker & Tayan, 2011; McNulty, 2014) review corporate strategy and major plans of action, engage in risk management, set performance objectives, monitor their implementation, and assess corporate performance. The board is responsible for recruiting and compensating executives and gets involved in the succession planning. The board should also oversee the process of corporate disclosure and communication.

The board which is composed of educated, competent, and experienced directors is viewed as an important corporate governance mechanism that can significantly contribute to the company development and increase shareholder and stakeholder values.

Composition and Structure

Directors Types

The composition of the board is viewed as its essential characteristics which determine the quality of its work (Tonello, 2010). From the perspective of the resource dependence theory (Pfeffer & Salancik, 1978; Davis and Cobb, 2010), the decision about who is appointed to the board is the crucial designation. Human capital represents an

important resource which can enhance the development of skills and competences and improve the quality of management and supervision. The board capital adds to the advisory capacity and oversight capacity (Larcker & Tayan, 2011) and is the source of competitive advantage (Sirmon & Hitt, 2003). Specifically, the director contribution refers to (Hillman & Dalziel, 2003; Pfeffer & Salancik, 1978): (1) advice and counsel, (2) legitimacy, (3) channels for communicating information between external organizations and the firm, and (4) preferential to commitments or support from outside the firm.

One-tier board is a collective group of different directors. Among board directors the following types are identified:

- Executives are managers appointed at the executive positions of the company. Although formally they are to be monitored by the nonexecutive directors of the board, in one-tier model they are also members of the board taking part in its work and discussion.
- Nonexecutives are the members of the board who do not have the executive positions in the company. In practice nonexecutive directors are recruited from independent directors, employees, outside, and constituency directors as well as affiliated or shadow directors.
- Independent directors are defined as directors who have no material relationship with the listed company (either directly or as a partner, shareholder, or officer of an organization that has a relationship with the company). In addition, according to the NYSE standards independent directors cannot have any present or past relations with the company (e.g., advisor, lawyer, former executives, or former employees), work as an employee or a manager, and receive compensation from the company of a given size. The necessary condition to be an independent director in a one-tier board is to be the nonexecutive and outside director. Yet, not all outside and nonexecutive directors have the status of the independent member of the board.
- Affiliated directors are nonexecutives who do not have the status of the independent member

of the board meaning that they do have some material relationships with the company. Affiliated directors are usually recruited from shareholders, suppliers, creditors, employees, or family relatives of the executives.

- Constituency directors are the members of the board who represent stakeholders such as NGOs or communities. Constituency directors are not often found on boards.
- Inside directors are directors who work in the company such as employees or executives.
- Outside directors are directors recruited from outside of the company.

In addition, the literature distinguishes the difference between the so-called *de jure* directors, *de facto* directors, and shadow directors. The *de jure* director is the director who is formally appointed to serve as the member of the board. The *de facto* director is defined as the person who fulfills the responsibilities of the director but is not revealed as a formal member of the board. In contrast the shadow director is a person who is not formally a member of the board but who provides instructions and guidance to the *de jure* director. The shadow directors are usually found amongst large shareholders who do not sit personally on the board but appoint the representatives who would execute their instructions. The shadow director may also be a politician or a member of the government who appoints another person to be the *de jure* director.

Board Committees

The board work encompasses a wide range of functions and tasks. Although the board acts as a team and is collectively accountable for its actions, the board work tends to be divided into topics and delegated to specialized board committees (Rezaee, 2010; Stiles, 2014). The trends to form committees is currently a well-recognized and recommended practice as it increases the engagement of directors with certain expertise (e.g., audit, remuneration), simplifies coordination of the board work, and assures a given degree of independence (when the committee included only nonexecutive or independent directors).

Formally, the committees are usually composed of 3–6 board directors focusing on specialized tasks. The number and types of committees functioning within the board differ depending on the company's practice and bylaws, its industry, and governance challenges (risk, succession, anti-trust regulations).

The most popular committees which function within the board include (Larcker & Tayan, 2011; Stiles, 2014; Tricker, 2012): audit committee, remuneration committee, nomination committee, strategy committee, and risk management committee. The tasks of the committees are precisely defined with the description of the procedures and policies of their work known as committee charters. The detailed description of selected committees' work is provided in the section of the Encyclopedia on two-tier board.

Interlocking Directorates

Board directors are experienced and well-educated individuals. Since they possess scarce resources (knowledge, competences, and professional contacts), they serve on many boards. The existence of multiple board mandates is a worldwide phenomenon. According to the resource dependency theory, in order to ensure the company survival managers build complex structural links among corporations (Hillman & Dalziel, 2003; Pfeffer & Salancik, 1978) such as interlocking directorates. These relationships enable efficient information flow and allow for cooperation and resources exchange.

Directors with numerous board seats are often former or current CEOs who understand the business and executive work as well as have the industry expertise (Lester & Cannella, 2006). Their appointment may add to the quality of the board work. It can also serve as a signal to investors that competent and well-experienced directors known for their good reputation protect their interests.

Interlocking directorates are believed to contribute to the socialization of new directors, increase the information flow, and help the exchange of experience. Yet, they are a subject of criticism due to the risk of the conflict of interests deriving from the participation in many

boards (e.g., competing companies), the inadequate time for preparation before the board meetings, or the consolidation of decision, power, and control in the hands of a relatively small group of people (Yiu et al., 2014).

Structural Shortcomings

The unitary board assumes that directors who play different functions in the company collectively participate in the board. This means that executive and nonexecutive, outside and inside directors work together to provide monitoring and counsel to the company. The board directors may serve as chairman and vice-chairman of the board, secretary, chairmen of board committees, and regular members of the board and board committees.

The effectiveness and the quality of the board work depend critically on the attitude and commitment of its chairman (Dalton et al., 1998; Larcker & Tayan, 2011). The role of the chairman is to assure for effective leadership, organization of the agenda and functioning of the board, setting high standards of work (directors are prepared, supplied with necessary data and information, and are active during meetings and executive sessions). The role of the board chairman is particularly important in the case of the one-tier board since majority of directors are recruited from outside of the company and may not have adequate information, particularly as confronted with executive on the board (Tricker, 2012). This may limit the monitoring role of the outside directors and deteriorate their contribution to the oversight over executives and the company.

The best practice for corporate governance calls for the independent chairman or lead director and suggests that the functions of the chairman and the CEO should be separated. Yet, in majority of US companies these two functions are combined, while the UK companies predominantly separate these positions. The criticism of the American boards refers to the dominance of the CEO-Chairman who possesses significant control over the agenda and may have excessive influence on the board work, also in areas of performance

evaluation, review of strategic goals, and monitoring.

In addition, the participation of executives and nonexecutives in one-tier board may add to the quality of communication and increase the flow of information (Tricker, 2012). However, one of the main weaknesses refers to the reluctance of the outside directors to openly criticize management or question some of companies activities. Such an open discussion is usually facilitated when executives and nonexecutives work separately as it is offered by two models. Hence, since the presence of executive directors in one-tier board may cause some distortions in the discussion about audit or executive compensation issues, the board committees are formed. The recommendation to have majority of independent directors in audit and remuneration committees is believed to address the problems of possible excessive impact of executives in the boardroom.

Another aspect discussed with the reference to structural shortcomings of the one-tier board points at the form of so-called staggered or classified board. Such board reveals a specific characteristic that distinguishes and divides the directors into groups (classes) with each class serving for a different term longer than the other. During the elections not all directors are appointed but shareholders vote for board seat which is vacant. Staggered (classified) board has become a popular practice in the US corporations. It is however criticized for being counterproductive for empowering shareholders and limiting investor influence over corporate governance.

National Versions

One-tier board is adopted in many companies. Although the general construct is similar and is based on the work of executive and nonexecutive directors in the same collegial body, the comparative analysis reveals significant national differences with respect to the board characteristics, structure, and practice. Below a brief characteristic of board in selected countries is presented (Mallin, 2004; Monks & Minow, 2004; Tricker, 2012):

- The American board of directors consists of on average 12–14 members among whom 1–3 directors are executives, 23% of directors are affiliated directors, and over 50% are independent directors. Female members make ca. 25% of members of the board. All listed companies form audit and compensation committees, while the functions of the Chairman of the board and the CEO are often combined. The board needs to comply with strong transparency standards as stipulated by the US regulations.
- The British board of directors consists of on average 10–14 members with the significant role of independent outside directors, participation of constituency directors (ca. 7%), and the female directors (approximately 20–30%). Unlike their American peers 90% of British companies keep the CEO and board chairman positions separate. All listed companies form audit and compensation committees. The board needs to comply with strong transparency standards provided by law and codes of best practice.
- The Japanese board of directors reveals far different characteristics as compared to its Anglo-Saxon counterparts. Japanese boards are composed of the vast majority (90%) of insiders, with participation of bank representatives and marginal presence of independent and female directors. The board work is determined by its distinct culture and strong hierarchy.
- The Indian board of directors functions in the context of the emerging economy characterized by the insufficient investor protection and weaker institutional order. Indian companies reveal ownership concentration which naturally impacts the practice of the board. Yet, according to the Securities and Exchanges Board of India (SEBI) the presence of independent directors should account for one-third of the directors on boards. The majority of boards form audit and compensation committees.
- The Russian board of directors operates in a different context than the US and British companies characterized by ownership concentration, lower transparency standards, and in selected companies also influence of the government. The board composition reveals strong position of the CEO and lower presence of

independent directors – ca. one-third of companies do not have any independent directors on boards. Yet, a vast majority (70–80%) of the boards form audit and remuneration committees, respectively (Kostyleva & Lehuedé, 2012).

- The Chinese board reveals a slightly different characteristic which appears to resemble more one-tier than two-tier model. Yet, the board has a hybrid structure aligned to the Japanese model. Structurally, the Chinese board encompasses the board of supervisors, the board of directors, and the group of CEO with general managers. The board of supervisors oversees finances and strategic development, nominates external auditor, and evaluates the performance of executives.

Trends and Best Practice

The board work is a complex task that covers numerous company issues of strategic, legal, investment, and financial character. The board is responsible for a number of decisions and actions, needs to coordinate its work, and comply with a number of requirements and guidelines.

Studies on composition, structure, and processes of the board remain an important stream of research in corporate governance, strategy, and finance. Numerous studies (Bear et al., 2010; Hafsi & Turgut, 2013; McGuinness et al., 2015; Nielsen & Huse, 2010; Terjesen et al., 2009; Terjesen & Singh, 2008; van Knippenberg et al., 2007) aim to understand the role and importance of selected board attributes such its size, structure, demographics, turnover, independent/affiliated directors, specialized committees for company performance measured by financial results, market position, and CSR/environmental performance.

In recent years the board of directors experienced structural and procedural changes. The most important aspects refer to the growing role of independent directors, board diversity, the impact of stakeholders on the board's focus and tasks, and the growing need for continuous training and development of directors. Firstly, studies report the growing presence of independent directors. This trend is growing despite several shortcomings

of independent directors. Independent directors are found not to have sufficient understanding of the industry specificity, and to lack experience and personal engagement. However, their participation on board is believed to assure objective and effective monitoring of executives (Pye, 2014). Secondly, the recent years note a significant increase in the board diversity. This trend results from the growing understanding of stakeholder expectations as well as new guidelines on increased women participation. Following the research which indicates a positive effect of board diversity on the quality of its work, companies include women and directors on greater international exposure to serve as board members (PWC, 2017). Thirdly, the board agenda evolves in response to growing stakeholder roles and incorporates the wider perspective on the company reporting and performance (Tricker, 2012). Topics on environmental protection, climate change, income inequality, and cyber security are added to the board agenda. Fourthly, numerous guidelines to increase the quality of the board performance are in place. The understanding on the board processes and dynamics adds to the implementation of the productive procedures to increase the efficiency of the board (McNulty, 2014). A more detailed discussion on these trends is provided in the Encyclopedia in the section on two-tier board.

Comparative analysis delivers a number of observations on the performance and dynamics of the board. A recent report by PWC (2017) enumerates the key trends and challenges for the board of directors:

- Need for changes among board directors – the report reveals the disconnectivity between board directors based on the differences in the quality of their monitoring and engagement in the board work. As noted “46% of directors believe that one or more of their fellow board members should be replaced. One-fifth of directors say that two or more directors on their board should be replaced” (PWC, 2017:2).
- Increased action to impose performance assessments in response to investor

expectations. In result, as the report shows, 68% of boards declare taking some action in response to their last assessment and reacting to the results achieved.

- Despite investor expectations only 60% of board directors challenge management assumptions on strategy.
- The presence of the independent chair makes a difference in the board monitoring and challenging board decision. According to the report boards with nonexecutive chairs are twice more likely not to re-nominate a director or to provide counsel to a director.
- Many boards still lag behind with respect to the process of prioritizing their goals. Particularly, still environmental and social issues remain neglected even with the growing awareness and interests expressed by investors. The report shows that many directors do not consider issues such as income inequality (51%), immigration (49%), and climate change (40%) important enough to be included in the board agenda and company strategy.
- Board diversity may deliver a more complex view of the company actions – as the report documents female directors pay more attention to social and environmental issues the in company strategy formation.
- Male and female directors differ also in the opinions of the effect of board diversity on performance – the positive impact is identified by 82% of women and 54% of men.
- While directors find long-term incentive plans to be efficient in promoting shareholder value, 70% of them believe that executives in general are overpaid. According to 66% of directors executive compensation strengthens income inequality.
- Shareholder engagement has a positive effect on corporate governance with the reference to proxy voting, investment presence, and preparation at the shareholder meetings.

One Tier and Sustainability

In line with the growing importance of the sustainability viewed as the essential component of a

company strategy and the need to improve ESG performance, the board adjusts accordingly. Recent studies indicate that the board structure and composition may serve as important drivers to increase ESG performance. In particular, the presence of independent directors as well as the representation of female directors on the board is found to add to ESG performance and disclosure. In addition, studies indicate the crucial role of the operation of CSR or sustainability committee within the board as well as the orientation of the board chair. Sector reports reveal that taking into account the nature of the board work, its directors need training in the area of ESG disclosure and sustainability.

Definition

Online communities are computer-mediated online forums where people gather to exchange text or audiovisual content in order to discuss, exchange information, or learn about topics that interest and concern them (Kozinets 2010; Schulz et al. 2018). These forums tend to develop through the initiative of citizens who like to engage with each other on a specific topic or (societal or personal) issues. Organizations build online communities to engage with their stakeholders. For example, a sustainable public or private organization can build a community via a Facebook group and a YouTube channel or through a corporate blog. Thus, online communities can be hosted or set up via various online platforms, internally and externally. An essential characteristic of online communities is that the participating actors share their thoughts, ideas, and information with like-minded others through public and private communication. Examples are citizens who may share and discuss their personal views and experiences on sustainable consumption, inspire each other, or evaluate sustainable organizations and their products and services. Organizations may employ online communities to legitimize their products, services, and actions and provide a shared space for their stakeholders to answer general and specific

questions concerning the organization. Organizations and citizens may gather jointly to promote ideas, get answers, criticize, or provide tips for improvements. It also means that organizations can take part in discussions within their online communities and those built by others relating to their organization or their area of interest.

Key Issues

Important elements of online communities are that users of such online platforms are able to exchange their thoughts and ideas with like-minded others. Therefore, they have become essential for all kinds of sustainability initiatives in the past decade, for example, to stimulate ethical or fair consumption (Gummerus et al. 2015). Online communities can be distinguished in different forms, organizational-, individual-, or group-driven:

Organizational or brand community: established by an organization to invite employees and/or stakeholders (e.g., consumers) to provide feedback on products and services. These communities can be public (accessible for everyone, for instance, a group page on Facebook or corporate blog that allows visitors to engage via commenting) or private (upon invitation only as part of a closed network such as corporate intranet or website). Organizations can also use these communities to legitimize their products, services, and actions (see ► “[Legitimacy Theory](#)”). At the same time, a corporate blog or Facebook page can also be a “frontstage” where critical stakeholders can share their concerns about an organization, its products, or actions and may influence other visitors and participants (Lillqvist and Louhiala-Salminen 2014). However, a brand community can also be established by “fans” of a certain brand who share personal information and experiences about the brand with others online, for

example, via a brand-dedicated Facebook group.

Special interest community: these online communities (also highlighted as communities of practice) are usually established by a group of individuals with the same interests in order to “. . . share and discuss written and audiovisual content based on special interest topics: for example, blogs or Facebook groups related to health, beauty, or politics.” [. . .] “Like other social media, these online communities provide (1) the possibility to post and reply to messages and (2) moderation by administrators. However, they distinguish themselves from other social media because they enable authors and participants to (3) share and discuss in-depth information and (4) ask and answer in-depth questions about special-interest topics” (Schulz et al. 2018, p. 291). Often these communities are publicly available. This means the shared content is visible for both visitors and participants. Visitors are actors who visit the community and go through the content (text such as blog post and comments or visuals of products) without interacting with other group members. Participants are visitors who join the group discussion or share their questions or information with others via the community. Visitors and participants seek information about a specific topic, for example, how to install solar panels or how to establish a sustainable lifestyle. They are able to join the conversation with others in order to share their questions, knowledge, or opinion about a specific topic. However, some groups have group administrators who “grant” access to others in order to be able to contribute to the group conversation. Examples are online forums where participants ask questions or share their opinions about certain sustainable products, such as natural cosmetics or organic food. Participants of these groups can choose an anonymous username (nickname) or use their own name to participate in these online communities.

Influencer community: individuals who share their thoughts and opinions on a (sustainable) subject are often the initiators and drivers of influencer communities. People gain an influencer status when their channel has many followers and/or page views. There are various platforms that influencers use to share content with visitors and participants. Popular platforms are Instagram, YouTube, and blogs where influencers share visuals, text, and video with a large audience. On YouTube influencers can be categorized into “vloggers” and “YouTubers.” While vloggers mostly share personal information and their daily thoughts and experiences, YouTubers share their opinions, experiences, and thoughts about specific topics such as food or cosmetics. As a result, these influencers are often perceived as experts by their followers, for example, by providing tips on how to live more sustainably (Schulz et al. 2019). While vloggers are more focused on sharing their daily life routines, YouTubers aim to share their ideas on a hobby or a way of life. However, influencer communities may have close relations with special interest communities as the influencer and his or her participants may share in-depth information and questions with each other.

Peer-to-peer or sharing community: participants of peer-to-peer communities aim to share goods and services through practices such as renting, swapping, lending, or borrowing (Vaskelainen and Piscicelli 2018). Examples are a car sharing system or communal sharing services for secondhand goods. These groups can have commercial interests or may support others by sharing their goods or services for free. Examples are specific apps to share transportation, food, or secondhand clothing. Individuals (e.g., via a website), groups of individuals (e.g., via a Facebook group), or organizations (e.g., via mobile telephone apps) can operate these peer-to-peer platforms. These communities often include rating and comment systems providing the participants with the opportunity to give feedback on other participants with whom they have shared an activity or

from whom they have received goods or services.

Third party review and rating community: these communities are often established by commercial organizations in order to provide a platform through which actors with the same interest can share their reviews of an organization, a product, or services. For example, users of Google Maps are able to provide a review of a specific “spot” such as a hotel or restaurant and add a star rating. Other users of these apps can then consult these reviews while seeking information about specific accommodation or a restaurant. Organizations are also able to reply to reviews from others.

Table 1 Provides an overview of the different characteristics of these different types of online communities.

Summary

Trust and credibility are essential elements in all of these community types. Organizations, individuals, and groups have to trust each other while sharing information with one another. Consequently, online communities often make use of user ratings and reviews. However, in smaller communities, such as special interest communities, participants may build trust through the exchange of in-depth contributions and a sense of friendship and connection which emerges with other participants. Influencers, however, build trust by sharing personal information with their followers. Moreover, credibility develops through transparency, for instance, when an influencer admits that he or she was sponsored by a certain company to produce a product review. Recently Fisher (2019) pointed to the opportunity for organizations gain a competitive advantage through their participation (e.g., by sharing information) as key stakeholders in their own or external online communities.

The question remains where and how organizations are able to cope with critical responses from their stakeholders. Online social media

Online Communities, Table 1 Characteristics and types of online communities

Community type	Initiator: Individual or group	Aim	Characteristics	Example of platforms
Organizational or brand community	1. Organization 2. Brand community: (a) Subdivision of an organization (b) A group of users (fans of a specific brand)	Organizations (1, 2a): to inform, interact, and engage with stakeholders To answer questions or provide webcare Construct and defend legitimacy Fan group of users (2b): who share their experiences with or artefacts from a brand	Organizational (1, 2a) Commercial (1, 2a) Noncommercial (2b) Non-organizational (2b)	Twitter Facebook group Instagram Corporate blog LinkedIn Corporate app Website Online forum
Special interest community	Group of individuals with the same interest or practice	To share ideas and discuss a joint topic or practice such as a hobby, a way of life or common interest	Non-organizational Noncommercial	Facebook group YouTube channel LinkedIn Online forum Group blog Reddit
Influencer community	Individual who shares his/her opinions and experiences on a specific topic and/or practice	Influencer shares his/her thoughts and stories about a specific topic. Community develops through interaction with followers (participants who provide comments engage with each other and feel committed)	Commercial Noncommercial Organizational Non-organizational	Personal blog Instagram Facebook Twitter YouTube channel
Peer-to-peer community	1. Group of individuals who aim to share in order to support others 2. Organizations that provide a service as part of business model	These noncommercial communities aim to share goods and services though sharing economy practices (e.g., food sharing to fight food waste) Other communities have (minor) commercial and use a sustainable business model (e.g., car sharing)	Noncommercial (1) (Minor) commercial (2)	Facebook group Website Online forum Mobile app
3rd party review and rating experience communities	Third party app developer/providers	An organization builds an online community to provide a platform to share firsthand experiences with another organization. For example, by rating hotel accommodations and by providing personal observations and experiences about an organization or service	Commercial Noncommercial	Apps that provide the possibility to rate or review other organizations and their products and/or public or commercial services

monitoring systems are already able to support organizations to identify where stakeholders discuss organizational issues in online communities. At the same time, organizations have to decide how they want to engage with others in their own and external communities,

for example, by answering questions, providing (customer) support, sharing expert information about their products and services, or discussing critical comments from customers. As there are many and various forms of online communities available, organizations have to make a wise selection of those in need of their support and willing to accept the engagement of an organization. Legitimacy (see ► [“Legitimacy Theory”](#)) may be at stake if an organization just steps into a discussion, and it may be costly to maintain active engagement with many different communities. In the future artificial intelligence technologies may be a solution to monitor and address consumer questions on a broader scale, for example, through automated replies. Nonetheless, many online communities are driven through the direct and personal contact among (human) participants.

Operational Ethical Dilemma

Ioannis Φ. Panagiotopoulos
University of the Aegean, Chios, Greece

Synonyms

OED

Definition

Operational Ethical Dilemma (OED) is a term introduced by Panagiotopoulos (2020) that delineates the situation amid the top management team of an organization must run a multiple criteria decision-making process whether a Corporate Social Responsibility (CSR) strategy will be implemented. This is a very crucial question that precedes any other decision for the details of the design and pursuance of any specific CSR activity. The answer to Operational Ethical Dilemma will define the implementation/continuation or not of such a strategy. The Operational Ethical Dilemma represents not only a question but highlights a situation where multiple parameters intervenes. Furthermore, OED marks the necessity of a process for the assessment of a CSR strategy and the investigation of the correlation between Corporate Social Performance (CSP) and Corporate Financial Performance (CFP). Especially strategic type of CSR considers CSR as a complicated system which demands notable inputs, and it is expected to produce significant outputs in favor of both stakeholders and the firm itself. Thus, it would be hypocritical or naïve CSR not to be considered by using scientific and business terms within a multiple criteria decision-making process.

Introduction

The transformation of companies from their preliminary forms they were used to have during nineteenth and the first half of twentieth century

into organizations with economic, social, and environmental action has started during the second half of twentieth century and it is ongoing so far. Basic element for this developing process is the concept of sustainable development which is spreading in every aspect of global economy. The need for turn to sustainable development has produced the idea of Corporate Social Responsibility (CSR) as a call to every company to reconsider its multiple roles inside the modern economic, social, and environmental framework. However, the involvement of a company into CSR activities is not that simple and especially in the case of strategic CSR, the development, implementation, assessment, reconsideration, and improvement of a CSR policy demands closed follow-up and continuous communication with stakeholders because it should not be taken for granted that every CSR program is good and proper for every company at every point of time. Moreover, the fact that there is dispute concerning the impact of CSR policies on the profitability of an organizations intensifies the criticality of asking the proper questions prior of looking for the correct answers.

Description

Elements like the Corporate Social Performance (CSP) and its consequences on the Corporate Financial Performance (CFP) will affect the decision for the launch or continuation of a CSR strategy. Managerial discretion is another parameter that will keep a determinant role in the final decision. A couple of tough versions of Operational Ethical Dilemma are: a) when CSP is promoted and enhanced with valuable resources even without strong data that a positive effect on CFP will follow, and b) when CSR policy is abandoned in favor of short-term profitability of a firm.

Operational Ethical Dilemma as situation has the inherent characteristic to reappear even if it has been answered to the past. The expressed intention of an organization to fund, design, and implement CSR programs could be reexamined in a certain time concerning its intentions, the benefits to stakeholders and its financial return to the organization. At that certain point, several

questions will arise regarding CSP, CFP, and their interaction. The answer to such a critical question cannot be considered as given because CSR is initially and in a principal level a positive thing for public society. The suggested answer should be “it depends on the available data that are related with CSP and CFP” (Panagiotopoulos 2020).

Therefore, it is vital a CSR strategy to be accompanied by measurements that will describe the resources used for it, the results in favor of stakeholders in comparison with the expected results, the possible improvement in any corporate sector like brand enhancement, green corporate profile, customers’ loyalty, employees’ satisfaction, avoidance of fines or taxation, etc. It should be underlined that a CSR strategy is critical for an organization and demands precise measurements and reliable feedback. CSR is deemed an investment with various tangible and intangible potential benefits and corporations should not underestimate the feedback and the assessment of their efforts because valuable conclusions could accrue from them.

A measurement system for the assessment of CSR activities should be designed that fits to the special characteristics of the market where a company is activated and to the nature of the CSR policy. Very generic assessment tools are very difficult to be adjusted in the particularities of discrete markets or different programs. A proper CSR assessment tool should measure CSP and corporate social financial return providing to CSR team and top management a clear picture for the position of an organization concerning CSR and the impact of that policy to its financial status at least in short and medium term. Such a holistic tool could provide useful conclusions prior of a decision-making process for Operational Ethical Dilemma.

The human factor could significantly affect the outcome of Operational Ethical Dilemma since managers are moral actors. They must exploit such discretion as is available to them toward socially responsible results in every field of CSR (Wood 1991). They have personal responsibility as leaders of their organizations to inspire their teams and guide them towards sustainability. They are responsible to closely follow up CSR

programs and examine the feedback received from these activities. Their suggestions concerning CSR strategy should be well reasoned and supported with evidence about the interaction between CSP and CFP, along with moral reasoning. The process of implementation of a CSR program is not as simple as a philanthropic donation especially when it is embodied into a total corporate strategy. A detailed design should be made that includes analytically available resources, expected results and potential goals to be achieved and moreover suggested measurements of efficiency, recording of results, feedback from stakeholders, assessment of CSR policy, and methods for the detection of any financial impact to the company. There are two possible threats for a firm. The first is based on the intangible nature of possible effects of CSP either positive or negative, a characteristic that creates obstacles in measurement and assessment process. Secondly, there is a possibility CSP to be dissociated from the total performance of the company because in this case CSR will be disconnected from sustainability (Wood 1991, p. 708).

Corporate Social Responsibility Background

A critical element in the theory of CSR is the voluntary nature of relevant programs. CSR is mainly about the policies that are beyond the level that laws and regulations define. Legislation as a codification of acceptable and non-acceptable behaviors can guide the corporate activity and companies should align with the increased state control which aims to cause socially responsible corporate behavior and deterrence of irresponsible corporate behavior (Carroll and Hoy 2004). A company is socially responsible when it operates in accordance with the existed legal frame keeping a proper historic record of compliance and low score of fines, and moreover when it functions in addition with the minimum legal requirements and acts voluntarily to secure a high quality in its relations with stakeholders. CSR comprises all these ways that incorporate social and

environmental problems into the corporate strategy (Carroll 1998).

The theory of legitimacy is defined as a general consideration and belief that the actions of a corporate entity are proper and welcome inside a social system when they follow the norms, the rules, and the values of that. Communication is a critical factor for managing legitimacy. A corporation should pay attention to its communications with stakeholders and should develop skills to understand and comprehend their interests, fears, and concerns (Suchman 1995).

Strategic CSR or Strategy of Social Intervention is the combination of strategic targets of a firm with social benefits. Thus, companies try to align the production of profits with socially responsible actions that take care of their stakeholders. This socially responsible strategy recognizes corporate profit as motive and stakeholders are treated as means for the maximization of shareholders' wealth (McWilliams and Siegel 2011). Ethical corporate behavior often implies short-term financial cost, but it contributes with long-term benefits. These long-term benefits could have both tangible and intangible nature. Corporate reputation and customers' loyalty consist elements that cannot be registered in an annual financial statement, but they could generate money for a company and they could be cultivated through a successful CSR strategy (Jones 1995). It is common in modern markets that customers make their choices for products or services taking into consideration the environmental or social profile of the companies. However, the application of strategic CSR causes inquiries concerning the problems that may come up due to the satisfaction of stakeholders' interests taking into consideration that sometimes there is a conflict among them or even between them and the direct interests of the firm. Moreover, there is a difficulty for the quantitative estimation of the efficiency of CSR programs. Many researchers conclude that the short-term profitability of companies that have incorporated into their strategy social goals could be either increased or decreased. Many researchers believe that CSR investments imply profits backward to the firms only in long-term

(Jones 1995). It is anticipated that companies may invest in these CSR policies that seem to yield positive financial return rather than negative or neutral, and in shorter period as possible (Panagiotopoulos 2020).

Approaching Corporate Social Performance

Researchers in the field of CSR like Waddock, Cochran, Clarkson, Wood, and Carrol have enriched the theoretical background of CSR by developing the concept of Corporate Social Performance (CSP) the last decades of twentieth century bringing into the spotlight the intense of CSR endeavors of a firm and the effectiveness of them. CSP has been defined as the interaction among the principles of social responsibility, the process of social responsiveness and the policies that have been developed for managing societal issues (Wartick and Cochran 1985). Wood examining this definition has recognized the absence of the element of action that should be present since it is highlighted by the word "performance" of the term. Furthermore, she emphasized the lack of recognition of a system of processes rather than a single process. Moreover, she disagreed with the word "policy" since a corporation could develop CSP even without having a relevant CSR policy. Another misunderstanding that was highlighted by Wood was the dual interpretation of CSP. A company that has CSP has a positive impact on society and positive score and the reverse (Wood 1991). In real, a company with CSP should pass through an assessment process and this is the only way to receive feedback for its CSR activity and improve it. Consequently, Wood incorporated these notices in the previous definition of CSP and has suggested that CSP is an arrangement of principles, processes, and possible outputs. A commercial organization focuses on the principles of social duty: a) in institutional (legitimacy), b) in organizational (public responsibility) and c) in individual (managerial discretion) level. The processes of responsiveness are: a) environmental assessment, b) stakeholders management, and c) issues management. The outcomes are defined as

a) social impacts, b) social programs, and c) social policies (Wood 1991, pp. 694–698).

CSP could offer a competitive advantage for a firm and added value to its products and services. These earnings for an organization depend on the expectations of their stakeholders although may have fluctuations. Companies hope to achieve better results in sectors like corporate fame and social image through the execution of CSR programs. The development of indices and the finding of proper variables for the measurement of CSP is a great challenge for a firm (Carroll 2000). Rowley and Berman (2000) support that most measurements of CSP are not valid because they are one dimensional. The variety itself of tools and guides have been developed for the measurement of CSP indicates that there are issues with the measurability of this element (Orlitzky et al. 2003). There are measurements that are based on the categorization of public society because there are several social groups with discrete opinions, values, and concerns. In a proportional way, there is a segmentation in CSP: a) the quality and safety of products, b) the quality of management, c) environmental responsibility and d) social responsibility.

Corporate Social Performance Versus Corporate Financial Performance

A company should invest an important part of its budget for the design and implementation of a CSR strategy enhancing its social profile. This initially negative relation between CSP and the CFP due to the cost of implementation of respective programs challenges researchers to examine the validity of concerns about CSR initiatives and provide reasoning regarding a compromise between an investment in CSR and corporate profitability (McWilliams and Siegel 2011).

The people who are against the idea of CSR support that such investments are an extra burden for corporations which could comply with stringent standards than those that the current legislation defines. Furthermore, CSR actions like budget for the promotion of green corporate

profile and the communication with stakeholders, maintaining premises in non-thriving areas, extensive donations for philanthropies are considered reasons that corroborate the negative relation between CSP and CFP (McGuire et al. 1988). This may imply that firms that apply CSR policies accept a competitive disadvantage by adding an extra source of spending in their budget. This burden is considered heavier for medium and small size firms with limited resources, and therefore an important number of them regards CSR as a luxury. Big size firms and international corporations can more easily design CSR programs and take advantage from economies of scale, investing in CSR programs without increase of their exposure in risk (McWilliams and Siegel 2011).

Another group of researchers regards that CSR has positive effect in the financial robustness of a firm. CSR strategy creates a potential for enhanced profitability through the improvement of corporate reputation because modern customers appreciate an ecological and socially oriented product (Duchin et al. 2010). Moreover, CSR should be treated as a long-term investment which empowers the more rational use of resources and means which harms less the environment, reduces accidents, and lowers the possibilities for fines (Panagiotopoulos 2020). Furthermore, the socially responsible companies perform better in depression periods because customers support them (Ducassy 2013).

An alternative opinion (Aupperle et al. 1985; Soana 2011) suggests that there are so many variables that affect the balance between CSP and CFP that it is difficult to extract a stable and absolute correlation either positive or negative. This may be the case in specific markets where specific variables that measure CSP could be considered as useful indices of CFP. The research has not managed so far to corroborate a totally positive relation between CSR and corporate profitability because there is high complexity and conflicting results from different studies. The creation of a complex measurement which could offer reliability to comparability, the subjective nature of self-reported indicators, the discriminatory questionnaires, and the self-assessment

responses as indicators of Corporate Social Performance, the multiple dimensions used to measure Corporate Social Performance and finally the incompatibility of comparative studies between different disciplines do not favor a general consent. In addition, the heterogeneity of variables and the characteristics of the business environment of each company and each industry are areas for the development of disagreements and conflicting views regarding the relationship between Corporate Social Performance and Corporate Financial Performance (Aupperle et al. 1985; Cochran and Wood 1984).

The mixed and conflicted results of relevant studies which tried to conclude on a positive, negative, or neutral sign for the interaction between CSP and CFP have left top managers without a clear gnostic base that could guide them to a specific direction. In any case, the contradiction of data possibly negatively affects CSR initiatives and prejudices a negative answer to operational ethical dilemma because uncertainty is not a covetable element in business world. Many researches have chosen to focus either on CSP or CFP and there are a few of them that have managed to study both in a balanced manner. However, most of the researches published between 1972 and 2000 in a level of 68% reveal a positive correlation between CSP and CFP (McWilliams and Siegel 2001). Moreover, it seems that a robust CSR policy that resists even in times of recession acts as an insurance for firms since there are evidences that companies with developed CSR strategy performed better during the global financial crisis of 2007–2008 (Ducassy 2013).

Conclusions

Rowley and Berman (2000) support that the relevant research about the interaction between CSP and CFP is encouraged by the wish of the provision of convincing reasoning that could be used by top managers to resist to corporate decision that are opposite to stakeholders' interests. Such gnostic background could offer them the wide

possibility to support the development of CSR strategy and the design of CSR programs that could facilitate societal and environmental issues even against the short-term profitability of the firm. Griffin and Mahon propose that the aforementioned factors could create a cognitive base that could guide from a deontology perspective top manager to orient their firms to sustainability (McWilliams and Siegel 2011). This cognitive background can extend our knowledge of the effects of the business environment on Corporate Social Performance and vice versa and increase our understanding of CSR activities under a variety of Corporate Financial Performance conditions.

Corporate hidden target for yielding financial profit through CSR policies may not be pure ethical. The pursuit of profit when it happens within the legal frame may not be ethical when is organized with the coverage of CSR policies. However, the implementation of CSR programs could produce positive environmental and social impact independently from the real motivation of a firm. In any case, the verification of real motives of CSR activities is difficult alike the measurement of CSP and could be any possible combination from philanthropic sensitivity of top management and/or shareholders, and the wish of a company to restore its relations with stakeholders after a scandal, up to green marketing and avoidance of tough taxation (Panagiotopoulos 2020).

Corporate Social Performance and the consequent Corporate Financial Performance in combination with the managerial discretion provide the outline of a situation where top management of an organization faces the challenge to make decisions for the design, implementation, funding, assessment, and improvement of CSR strategy. Thus, a new concept is defined, Operational Ethical Dilemma that describes the challenge and the question that every top management team must deal with.

Summary

Corporate Social Responsibility (CSR) has been developed significantly the last decades and

occupies important resources of a company. Moreover, firms expect benefits from Corporate Social Performance (CSP) and correlate CSR programs with several goals like green marketing, customers' loyalty, brand recognition, etc. that finally entail a positive addendum in their Corporate Financial Performance (CFP). The realization of CSR as a system with considerable inputs and outputs creates demands for a careful consideration of decisions related with the CSR strategy of an organization. Operational Ethical Dilemma (OED) comprises the situation amid top management of an organization should proceed with a decision-making process for the implementation of a CSR strategy. The weighting of demanded inputs and expected outputs, the assessment of previous CSR policies, the feedback from stakeholders, and the interconnection between CSP and CFP synthesizes a multiple criteria decision-making process. Finally, OED comprises the dilemma whether a CSR strategy should be implemented and the necessary steps that should be followed for a well-reasoned decision that drives a modern company toward sustainability and a fruitful relation with its stakeholders.

Synonyms

[Corporate culture](#); [Organizational development](#)

Introduction

In simple terms, the organizational culture refers to the set of values, beliefs, customs, and behaviors specific to the people working in an organization. Organizational or corporate culture represents an important area of management because of the role played in the organization's performance. Understanding the organizational culture helps someone from outside a company to understand the reasons behind some behaviors or decisions. Cameron and Quinn (2011) consider that people are not always aware of their culture, at least not until they are somehow challenged. The authors appreciate that there are observable (explicit behaviors, norms) and unobservable elements (assumptions). Keyton (2005, p. 53) defines organizational culture as the "congruence of artifacts, values and assumptions jointly held or shared" by the company's employees and managers. This unity is the essence of an organizational culture; it is what makes the people in an

organization stick together. At least this is the case with strong cultures, because there are different levels of organizational culture. In weak cultures, people are not so united and do not share the same values or are not so interested in those values. Morcos (2018) considers that organizational culture is tangible, makes the difference between successful and unsuccessful companies, and influences the spirit of the employees at work. O'Donnell and Boyle (2008) emphasize that the identity of an organization is given by its culture.

Dimensions of Organizational Culture

Hofstede (2011) identifies six dimensions of organizational culture: power distance, uncertainty avoidance, individualism vs collectivism, masculinity vs femininity, long-term vs short-term orientation, and indulgence vs restraint. The first four were already established since 1980 when Hofstede published the results of the research conducted between 1967 and 1973 within the world subsidiaries of IBM. The latter were added afterward after extending the research. Power distance refers to the way members of a structure (family, organization, society) accept hierarchy and inequality between different individuals. Uncertainty avoidance is about control and how people react in front of uncertainty and risks. Individualism reflects the interest of the individual and of his/her immediate family, while collectivism reflects people who are more prone to take care of others and follow the interests of all. Masculinity vs feminism refers to the prevalence of the traits considered more masculine or more feminine. Long-term vs short-term dimension refers to the importance of the past or the future for the present (some entities value more the past, so they have a more traditional approach, while those more oriented on the future and the changes that it brings have a modern approach, incorporating technology). Indulgence vs restraint refers to the way society encourages or discourages gratification of someone's needs and desires.

Jones (2007) emphasizes some arguments against Hofstede's classification: relevancy of surveys for such a sensitive subject like culture;

assumed cultural homogeneity (but a country has different ethnic subgroups); national division (culture exceeds borders); political influences (at the time of the study, the political context might have influenced the masculinity vs femininity dimension); approach limited only to the IBM situation; and outdated (the rapid changes nowadays might influence aspects of these dimensions. For example, masculinity vs femininity might not be considered politically correct today). Even if there were many critics of Hofstede's work, the dimensions of culture established by him helped us better understand the cultural differences between individuals, companies, and countries and created a starting point for other researchers.

Types of Organizational Culture

Cameron and Quinn (2011) identified four types of organizational culture, creating the model of the Competing Values Framework. This model helped them in developing the Organizational Culture Assessment Instrument (OCAI) which can be used by companies to establish the status of their culture. The four types are clan culture, adhocracy culture, market culture, and hierarchy culture.

Clan culture is characterized by loyalty, friendliness between the employees and managers, teamwork, and caring for clients and employees. There is a strong connection between those who work in such an environment. A disadvantage would be the lack of competitiveness between the employees that would bring progress and novelty in some areas. *Adhocracy culture* refers to those companies that embrace innovation and love to take risks; thus, the employees are encouraged to take initiative and be creative. They feel free to experiment with different ideas. The disadvantage might be that these environments might feel overwhelming and that they have to keep up with the others and always find innovative ideas to put into practice. *Market culture* is focused on results, competitiveness, and market penetration. The environment is very competitive, and the employees might feel pressured because they are goal-oriented and are expected to reach them

better and faster than their coworkers. *Hierarchy culture* is specific to companies that are “formalized and structured” (www.ocai-online.com/about-the-Organizational-Culture-Assessment-Instrument-OCAI/Organizational-Culture-Types). Rules, procedures, and policies determine what happens within the organization. The aim is to predict all outcomes and better control them. The disadvantage would be the lack of freedom and the limits put to the creativity of employees; innovation may suffer.

Levels of Organizational Culture

Schein (2010) created a model with three levels of organizational culture: artifacts, espoused beliefs and values, and basic underlying assumptions. *Artifacts* and symbols are what we can see at the surface of an organizational culture (clothes, logo, style, language, legends, rituals, and other elements that can be observed). *Espoused beliefs and values* refer to ideologies, values, goals, and philosophies. Ideally, these should be in accordance with artifacts and basic assumptions, but it is not always the case. Sometimes, they are “abstract ... and mutually contradictory” (Schein 2010, p. 27). *Basic underlying assumptions* explain behaviors and are unconscious and being hard to change. They became so ingrained in the culture after repetitive behaviors that proved to be successful. These types of assumptions are like patterns and usually they are not put under discussion; they are taken for granted. These levels influence the capacity to change the organizational culture within a company. Artifacts and symbols are the easiest to change, while assumptions are the most difficult to change. The stronger a culture is, the more difficult is to change it.

Steps in Changing the Organizational Culture

Organizational culture is not easy to change, and the decision to accomplish this should be thoroughly analyzed by the manager and planned accordingly in a process with multiple steps in

order to diminish the resistance to change from the employees. If the employees are reluctant to changes, the process will be difficult and will create problems. Alvesson and Sveningsson (2008, p. 44) present the six steps needed for a change of the organizational culture: evaluating the situation and establishing the goals to be accomplished; analyzing the present culture and establishing the desired one; analyzing the gap between these two; developing a plan for reaching the desired outcomes; implementing the plan; and evaluating the results and adjusting the strategy accordingly. Because culture gives an identity to the organization (O'Donnell and Boyle 2008; Martin 2013), any attempt to make changes will be perceived as a threat to the employees' safety. The manager should make his or her decisions considering this factor. Some of the measures that could be implemented in order to make the employees gradually accept the change are as follows: explain all the changes and the necessity to operate them; make the changes gradually not quick in order to give the employees time to adjust and accept them; really consider the feelings of the employees (people identifying with the company's culture might feel as they would have lost their own identity when leadership tries to change the culture); encourage feedback from the employees; and make a research to analyze the impact of the change on performance and productivity. Smollan and Sayers (2009) conducted a qualitative study to analyze the connection between the organizational change and the impact on the employees' emotions. Even if the study is not exhaustive, the emotional aspect should be considered by a leader that understands the importance of emotional intelligence.

Summary

Organizational culture brings numerous benefits to a company: identity for the employees (O'Donnell and Boyle 2008; Martin 2013; Kumar 2016); can attract potential employees (someone might want to work at a company driven by its culture); strong cultures motivate people to be more productive and create

competitiveness between the employees that might be beneficial for the overall performance; stimulates “creativity and innovation” (Szczepanska-Woszczyna 2014, p. 33); leads to a better image in the community, and attracts loyal customers and partners. Nukic and Matotec (2014, p. 26) consider that organizational culture is “one of the most significant determinants of the strategic development of an organization,” so the management of a company should try to create a strong culture as part of the company’s long-term strategy. It is a lot of work, and history behind the organizational culture and any decision to change it should be carefully revised in order to not create more damage than benefits.

Organizational History and Evolution of Principles for Responsible Investment (PRI)

Szilvia Mosonyi

Queen Mary University of London, London, UK

Description

In 2002, the United Nations Environment Programme Finance Initiative (UNEP FI) set up the Asset Management Working Group to work with a group of investment management firms on the topic of integrating environmental, social, and governance (ESG) factors into mainstream

investment. In April 2005, United Nations (UN) Secretary General Kofi Annan invited a group of institutional investors to draft a set of principles that would provide a framework for a responsible investment initiative. Following a drafting process, coordinated by the UNEP FI and Mercer, that lasted 11 months and included two meetings of 60 experts and three investor group meetings, a final list of ten principles of responsible investment was produced. The Principles for Responsible Investment (PRI) secretariat was set up in London with one employee (van der Lugt and Dingwerth 2015). This chapter describes key milestones in the organization's development and factors that enabled its success, PRI's relationship with the UN is clarified, and three ongoing challenges of PRI – signatory reporting, regional expansion, and policy work – are unpacked.

Genesis and Development of the Principles

The United Nations Environment Programme (UNEP) was set up in the 1970s to promote and help cooperation among United Nations (UN) member states on environmental issues (UNEP 2022). It was only from the early 1990s that the UN started to engage the private sector in its mission of sustainable economic growth. In preparation for the Rio Earth Summit in 1992, a small group of banks drew up the “UNEP Statement by Banks on the Environment and Sustainable Development” and launched the “Banking Initiative,” which a few years later was renamed the UNEP Finance Initiative (UNEP FI) and engaged the financial sector to integrate environmental considerations in their practices (UNEP FI 2022). This was followed by the launch of the UN Global Compact (UNGC) in 2000 to, in the same vein, engage the wider corporate sector in sustainable development (UNGC 2020).

In 2002, the UNEP FI set up the Asset Management Working Group to work with a group of investment management firms on the topic of integrating environmental, social, and governance (ESG) factors into mainstream investment. One

outcome of this working group was a report on the materiality of ESG issues in equity pricing (UNEP FI 2004) that was launched in 2004 at the first UN Global Compact Leaders' Summit in New York along with UNGC's own “Who Cares Wins” report (UNGC 2004). These reports established the relevance of ESG issues for mainstream investment and stressed the importance of engaging institutional investors (asset owners) to achieve systemic change. Institutional investors' significance stems from their power to exert influence on the finance value chain due to being majority shareholders in publicly traded companies and from the substantial growth of their managed funds over the years (Ryan and Schneider 2003). To act on the reports' recommendations, the executive director of UNEP announced the intention to launch a responsible investment initiative and published a project proposal within one month of the conference.

In April 2005, UN Secretary General Kofi Annan invited a group of institutional investors to draft a set of principles that would provide a framework for the initiative (PRI 2022b). UNEP FI engaged consulting firm, Mercer, to facilitate the drafting process that lasted 11 months and included two meetings of 60 experts and three investor group meetings that produced a final list of ten principles of responsible investment. The process was supported by the publication of the Freshfields report titled “A legal framework for the integration of ESG issues into institutional investment” that was commissioned by the UNEP FI Asset Management Working Group (UNEP FI 2005). Financial support for the process came from the private sector. The Principles for Responsible Investment (PRI), a principle-based membership organization, was launched by UN Secretary General Kofi Annan at the New York Stock Exchange on the 27th of April 2006 followed by a European launch at the Paris stock exchange. One of UNEP FI's team members, James Gifford, became the first executive to head the PRI secretariat in London (PRI 2022b).

The success of the process and the launch depended on the commitment and strategic insight of a handful of committed individuals at UNEP FI, UNGC, and investment institutions. The

Organizational History and Evolution of Principles for Responsible Investment (PRI), Fig. 1 PRI signatory growth: assets under management (US \$ trillion). (Source: PRI 2022b)

flexibility of UNEP FI to maneuver outside the UN bureaucracy, the increasing ESG expertise in the finance sector, and the legitimacy provided by the figure of Kofi Annan to convene business executives also played a key role (van der Lugt and Dingwerth 2015).

The number of members signing up to PRI's ten principles has increased substantially since the launch in 2006, from 63 to 3826 in 2021 accounting for a total of \$121.3 trillion assets under management (Fig. 1). The aftermath of the financial crisis (PRI 2009), the increased emphasis on the financial sector to deliver the Sustainable Development Goals (SDGs) in terms of capital required (Reynolds et al. 2021), and the voluntary nature of the principles (Bondy et al., 2012) all contributed to this growth. While pension funds used to dominate PRI's asset owner base, this has since diversified with insurance companies representing 60% of asset owner assets under management with increasing number of endowments, foundations, and corporate pensions (PRI 2021a).

PRI's Relationship with the UN

PRI "is supported by, but not part of, the United Nations" (PRI 2022a). The official label used is "UN-supported PRI." While the initiative was

spearheaded by the UNEP FI team and supported by the UNGC leadership, it has never gone through formal rigid intergovernmental endorsement (as the UNGC did) and always has had a low state-level oversight (van der Lugt and Dingwerth 2015). As such, PRI is less UN-driven and more consensus seeking among its membership. After its launch, the organization had a voluntary fee structure that was channeled through the UNGC foundation based in New York. This has changed after the incorporation of PRI in the UK in 2010 and the move to a mandatory fee model.

Coordination between PRI, UNEP FI, and UNGC has been strengthened by PRI's governance structure. Executive directors of UNEP FI and UNGC were offered a permanent seat on PRI Advisory Council from the start (van der Lugt and Dingwerth 2015). While the governance of PRI has changed substantially in the past 10 years, these positions remained steady.

PRI has stimulated corporate uptake of the UNGC principles through its own membership by either asking their investee companies to join the initiative or encourage leaders and challenge laggards in the UNGC space. UNGC and PRI had many joint programs during the years and even had a dedicated person in New York overseeing these. PRI and UNGC signatories has been working together in many collaborative engagements

between companies and their shareholders (Gond and Piani 2013).

Changing Governance Structure

Following its launch in 2006, the task was to develop an organization that can grow, manage, and cater for the needs of the signatory base. The organization initially grew slowly from one employee in 2006 to eight employees in 2009 but started to expand more rapidly to 53 in 2012 and 161 employees in 2021 (PRI 2022a). PRI faced two governance challenges in this process: how to govern a fledgling organization internally and how to set out a governance structure that provides appropriate representation of its signatories (asset owners, asset managers, and service providers).

First, the internal governance structure was made up of a small secretariat based in London and an advisory board of 11 asset owners and two UN representatives (PRI 2007). The move from voluntary to mandatory fee structure brought with it the need to provide representation to other types of signatories including asset managers and service providers. As a result, since 2011 the Advisory Council has included members representing different signatories (seven asset owners, two asset managers, one service providers) and different geographies (e.g., Brazil, USA, France, South Africa, Thailand), who were elected for a 3-year period. Candidates need to campaign to secure votes from their own signatory base to be elected (PRI 2022c).

The changing fee structure also meant that the organization could become independent from the UNGC foundation in New York and go ahead with its incorporation in the UK in 2010 as two separate entities (PRI Association and PRI Foundation). As a result of an expanding council and the incorporation, from 2010 to 2015, a smaller board of asset owners (4–5 members) took over the operational management of the organization, while the larger council (15 members) remained responsible for strategic directions. Signatories grew discontent with the lack of transparency around the changes and lack of representation in

the operational matters and voiced their concerns in the 2012 annual meeting in Rio de Janeiro. PRI announced a formal governance review a year after; however, seven signatories have delisted to show discontent. The organization initiated an extensive consultation process with signatories that culminated in a revised governance structure, terms, and policies. PRI returned to a single board structure of 12 members. Partly from this experience and from the extensive consultation on the PRI reporting framework, the organization has developed a strong culture of transparency and signatory engagement across various operational and strategy issues through intensive consultations and working committees (Gond and Piani 2013; Majoch et al. 2017).

Encouraging Signatories' Reporting on ESG: The PRI Reporting Framework

Signatories of PRI have an annual public reporting obligation toward the organization on how they implement the principles. They submit their responses to an extensive list of predetermined mostly qualitative questions, and PRI then publishes a summary analysis of these reports. The reporting framework has gone through various iterations since its launch in 2006 and has recently gone through an extensive review and consultation as part of PRI's 10-year strategy (Arjaliès et al. 2022). Sections of the questionnaire became mandatory in 2013 reporting on policies, resources, and processes (Sullivan and Fiestas 2012). There is now an increasing focus on reporting on performance outcomes and impact signatories have through integrating the principles. However, the organization does not have capacity to monitor compliance and hold signatories to account that has resulted in greenwashing criticism over the years. PRI started to assess the reports in 2014 and score the sections of submissions. Scores are confidential, but PRI showcases high-scoring signatories as part of its Leaders' Group based on changing themes every year (e.g., leaders in climate reporting in 2020). From 2020, PRI started to delist signatories, who fail to meet

minimum reporting requirements over a 2-year support period (Gibson et al. 2021).

The reporting framework has multiple functions. It drives accountability of PRI and its signatories. Investment managers increasingly provide these PRI reports voluntarily in competing for investment mandates from institutional asset owners (Gibson et al. 2021). The reports provide transparency over investor actions around responsible investment. Signatories' responses are evaluated, and they receive detailed feedback that helps their development in improving internal processes, in particular new signatories. Responses have been benchmarked against peers that also provide useful information for signatories. In the first year, new signatories do not have the obligation to report, but if they do, they can ask for their report to remain confidential.

Maintaining Global Relevance Through Regional Expansion

Throughout its development, PRI faced the challenge of achieving global relevance. The responsible investment market has a different history and culture geographically; as such, the organization needs to ensure that it is sensitive to local context. This was evident when the founding signatories from Australia, USA, Canada, France, Sweden, Germany, Norway, UK, and the Netherlands came together to draft the principles and remained so when the organization looked to recruit new members, raise awareness, and enable implementation across the globe.

This challenge influenced PRI's governance and organizational structure. Geographical diversity has always been a key component in the composition of its board, with the present board having representatives from Europe (4), USA (2), Japan (1), South Africa (1), Australia (1), and Canada (2) (PRI 2022c). When PRI was launched, European signatories comprised half of its members (80), followed by signatories from North America (24%). The proportion of these two regions has remained the same since; however, the share of signatories in Asia and South America

increased (10% and 5%, respectively), as PRI opened its regional offices over the years (PRI 2022e).

PRI's global presence has increased massively with staff present in 16 markets in 2021 and further aiming to add operations in Italy, South Korea, and India (PRI 2021b). The first three networks launched in South Korea, Brazil, and South Africa driven by local signatory demand and heavily supported by the largest local pension funds (e.g., PREVI in Brazil in 2008 and GEPI in South Africa in 2009). Local presence ensures faster expansion in the region by increasing awareness, sharing global best practice, offering techniques for ESG integration within the signatory organizations, and providing a local engagement platform (Giamporcaro and Pretorius 2012; Yamahaki 2019).

Supporting Systemic Change Through Policy Work

With the publication of its 10-year strategy (the "Blueprint") in 2016, PRI expanded its core mission of supporting, empowering, educating, and bringing together the investment community to work toward a sustainable global financial system. A new value-based approach adopted the UN SDGs and started to actively advocate for an enabling environment supporting investors to achieve their sustainable market goals (PRI 2016a, b). This approach is grounded in the knowledge that governmental interventions shape financial markets and mobilize them to promote responsible investment through regulating and forming standards (Giamporcaro et al. 2020). Of the 50 largest economies, 48 have a policy in place prompting investors to consider sustainability risks and opportunities (PRI 2019) with over 868 hard and soft law policy tools and guidance in existence (PRI 2022d). PRI published a regulation database of global sustainable finance policy in 2016 on its website and has been updating it periodically.

PRI is taking an active role in influencing governmental interventions in local and global

contexts. In 2021, the organization responded to 52 consultations and published 18 policy briefings in 15 markets (PRI 2021a). These included supporting the development of the European Union's sustainable finance taxonomy and sustainable corporate governance initiative, publishing "US Policy Priorities for 2021," and responding to consultations and organizing roundtables around the Task Force on Climate-Related Financial Disclosures (TCFD) for pension funds and listed issuers. In line with its culture of transparency, PRI publishes the content of all consultations and policy reports on their website. In addition to these activities, PRI – together with the World Bank – developed a tool kit for policy makers and regulators providing them support to implement reforms to build a sustainable financial system.

The organization also continues its reporting, research, and policy engagement on clarifying investor obligations and duties (fiduciary duties) in relation to the integration of ESG issues in investment practice and decision making. Following the 2005 Freshfields report (UNEP FI 2005), PRI published reports on "Fiduciary Duty in the 21st Century" in 2015 and 2021 (PRI 2020). In 2019, PRI along with UNEP FI and the Generation Foundation launched the "Legal Framework for Impact" work program and commissioned legal analysis from Freshfields Bruckhaus Deringer to determine the extent to which legal frameworks enable investors to consider impact in their activities across 11 jurisdictions (PRI 2021a).

Summary

The UN-supported PRI has developed from a list of asset owner principles in 2006 to a central player in changing investment practice in the investment industry (Reynolds et al. 2021). In its 16-year history, the organization moved from an informal start-up structure to a professionally governed multi-stakeholder membership association. Its signatories of asset owners, investment managers, and service providers are represented

on its board and jointly work towards their common goal of a more sustainable global financial system.

**Paradoxical Lens
in Sustainability Tensions:
Chinese and New Zealand
Partnerships**

Chen Sitong (Michelle) ¹ and Gabriel Eweje ²

¹Department of Management and International Business, The University of Auckland Business School, Auckland, New Zealand

²School of Business and Law, Edith Cowan University, Joondalup, WA, Australia

Description

Recently more and more Chinese and New Zealand companies have established business partnerships; however, while these companies joined to achieve financial success, they are also faced with difficulties in addressing sustainability issues. Hence, this entry empirically examines tensions in addressing sustainability activities and the reasons causing them between Chinese

and New Zealand firms in business partnerships. In doing so, in-depth semistructured interviews were conducted at 16 relatively large Chinese and New Zealand firms in business partnerships. We find that these companies are faced with multiple sustainabilities which partially overlap across individual, organizational, and societal levels in a knotted and nested relationship. Theoretically, we contribute to paradox theory by identifying the complex relationships among multiple tensions. We suggest to the practitioners that it is difficult to manage the sustainability tensions simultaneously, because moving one competing demand may affect another one.

Synonyms

Recently more and more Chinese and New Zealand companies have established business partnerships; however, while these companies joined to achieve financial success, they are also faced with difficulties in addressing sustainability issues. Hence, this entry empirically examines tensions in addressing sustainability activities and the reasons causing them. In doing so, in-depth semi-structured interviews were conducted at 16 relatively large firms and found that these companies are faced with multiple issues which partially overlap across individual, organizational, and societal levels in a knotted and nested relationship. Theoretically, we contribute to paradox theory by identifying the complex

relationships among multiple tensions. We suggest to practitioners that it is difficult to manage the sustainability tensions simultaneously, because moving one competing demand may affect another.

Introduction

This entry empirically examines tensions in sustainability and the reasons causing them between Chinese and New Zealand firms in business partnerships. As Chinese and New Zealand firms continue to develop partnerships, major challenges are anticipated around tensions in addressing sustainability issues. Accordingly, with the rise of organizations operating in global markets that explicitly address social and environmental problems (Govindan et al., 2021; Peters & Buijs, 2021), they may have contradictory sustainability practices (Rodriguez et al., 2021).

Tension in sustainability is a relatively new area and is largely unexplored empirically in business contexts (Govindan et al., 2021; Hahn et al., 2018; Hahn et al., 2016; Van der Byl & Slawinski, 2016). Joseph et al. (2018) asserted that empirical research on sustainability tensions is limited and thus requires future researchers to conduct more empirical studies in different industries and various contexts. Hence, the first research question is: *What are the pressing tensions related to sustainability that arise between, or within, Chinese and New Zealand business partnerships?*

Further, in the many existing studies exploring tensions in addressing sustainability issues between China and Western countries which focused on national-level investigations (Espa, 2018; Raine, 2009), most focused on the factor of cultural diversity (Vangen, 2017), as being influenced by different cultural roots, Westerners and Chinese decision-makers may have contradictory understandings of competing dimensions. While Chinese managers may tend to adopt “both/and” logic by seeing the connections between or among opposing aspects, Western managers may use “either/or” logic by prioritizing one perspective over the other (Keller & Loewenstein, 2011; Keller et al., 2017). However, it is difficult to find

any empirical study investigating this perspective in the sustainability research field (Waldman, Putnam, Miron-Spektor, & Siegel, In press). Therefore, the second research question is: *If tensions exist in sustainability between Chinese and NZ firms in business partnerships, then what reasons might be causing the tensions?*

Against the above background, it is timely and necessary to investigate tensions in addressing sustainability issues in the context of Chinese and New Zealand firms in business partnerships and the reasons causing them. This chapter contributes to scholarly understanding of identification of the tensions and their complex relationships. In addition, based on practitioners’ interpretations and theoretically supported by literature, it is expected that this chapter can provide practitioners in better managing tensions by addressing divergent sustainability issues simultaneously.

The rest of this entry is structured as follows: The theoretical background conceptualizing holistic sustainability is explored through literature that investigates tensions in sustainability in business contexts. Thereafter, this entry reviews the reasons causing them. Then, the empirical study’s research design is described, and the results of this study are provided. The discussion section interprets our novel insights on tensions in sustainability and the reasons causing them. The entry concludes with limitations and suggests opportunities for future scholarly exploration of tensions in addressing sustainability issues in business contexts.

Literature Review

Apply Paradox Theory into Tensions in Sustainability

In recent years, there has been an increasing amount of literature on tensions in sustainability in business contexts (Chen & Eweje, 2022), which can be illustrated from the following three sustainability areas: strategic, intertemporal, and instrumental and moral tensions.

First, Smith (2014) defined strategic tensions “as contradictory, yet interrelated, demands

embedded in an organization's goals" (p. 1592). According to Edwards (2021), most firms have experienced strategic tensions within their organizations, because decision-makers often have contradictory strategies in addressing environmental, social, and economic performance. Hahn et al. (2018) further asserted that these kinds of tensions touch the very heart of sustainability, because they involve a diverse set of potentially competing sustainability issues, such as climate change, biodiversity conservation, poverty alleviation, public health, and education.

Second, as required by WCED (p. 43), firms should address short-term business targets and long-term societal goals at the same time. This indicates that the long-term nature of the benefits that a business provides to the society may be in conflict with short-term business benefits for organizations (Carollo & Guerici, 2017; Slawinski & Bansal, 2012, 2015). The short-term versus long-term tensions were named by Slawinski and Bansal (2015) as "intertemporal tensions" (p. 531): when "the demands of today differ from the needs for tomorrow" (Smith & Lewis, 2011, p. 389).

Third, citing Margolis and Walsh (2003), Hahn et al. (2016) proposed that firms are faced with tensions in addressing instrumental and moral initiatives. They argued that firms focused on instrumental initiatives are essentially driven by organizational benefits, so social issues are only considered if they can bring organizations some economic benefits (McWilliams & Siegel, 2011). In contrast, firms which are driven by moral initiatives ensure that their organizational activities are based on the moral aim to "do the right thing." Firms thus "rest upon fundamentally different and contradicting foundations – i.e. the business case and the moral case, respectively – which gives rise to considerable tensions" (Hahn et al., 2016, p. 214). Similarly, Ashforth and Reingen (2014) investigated the ideal and pragmatic tensions in a natural food corporation. They found tensions between two major informal groups whom they labeled "idealists" and "pragmatists" (p. 479). They found that "idealists endorsed social idealism such as cooperative and environmental values more strongly than did pragmatists, whereas

pragmatists endorsed financial viability more strongly than did idealists" (p. 479).

To better understand the tensions in sustainability, scholars have applied paradox theory. According to Schad et al. (2016), paradox theory is rooted in both Western and Eastern philosophy. In fact, they defined paradox in management as "persistent contradiction between interdependent elements" (p. 10). This definition clarifies two core characteristics of paradox: contradiction and interdependence, as illustrated below.

Early scholars have attempted to argue that paradox denotes a contradictory perspective of diverse competing demands (Niesten & Stefan, 2019; Prashantham et al., 2018). Poole and Van de Ven (1989) described paradox as "interesting tensions, oppositions, and contradictions between theories which create conceptual difficulties" (p. 564).

However, other scholars asserted that paradoxes depict the complicated connections among opposing elements, highlighting their interdependent nature (Periac et al., 2017). Early scholars suggested these inextricable links between opposing elements. Cameron (1986) discovered that contradictory elements are able to operate at the same time, because there is no complete separation among the opposing elements. Similarly, Smith and Berg (1987) explained that "the contradictions are bound together, the more that members seek to pull the contradictions apart, to separate them so that they will not be experienced as contradictory, the more enmeshed they become in the self-referential binds of paradox" (p. 14). In fact, these definitions express the coexistence of divergent competitive demands which emphasizes their synergistic relationships (Efrat et al., 2022; Kourti, 2021).

When it comes to its application in tensions in sustainability, paradox theory provides a better understanding of tensions in sustainability and their complex relationships at Chinese and NZ firms in business partnerships. A paradoxical perspective on sustainability embraces "tensions to simultaneously accommodate competing yet interrelated economic, environmental, and social concerns that reside at different levels and operate in different logics and time frames and in different

spatial scales” (p. 236). On the one hand, the competing environmental, economic, and social dimensions are contradictory to each other; however, at the same time, they are also interdependent elements which emphasize their interplay as one can transform into the another.

Reasons Causing the Tensions in Sustainability

Prior research suggested that when members have different opinions on what is central, enduring, and distinct about their organizations, conflict and tension proliferate (Sheep et al., 2017). In other words, tensions in organizations may surface when members disagree about which attributes characterize their organizations (Glynn, 2000; Pratt & Rafaeli, 1997). Drawing from this view, an increasing number of studies have pinpointed that tensions in sustainability may appear in firms when their decision-makers have divergent values and views regarding sustainability (Van der Byl & Slawinski, 2016). For example, Qiu (2005) argued that tensions between Chinese and foreign firms in joint venture business partnerships in Shanxi province such as staff recruitment and training, dismissal, energy supply, and a development agenda resulted from differences between foreign and Chinese top executives. Similarly, Ashforth and Reingen (2014) found that tensions exist in a natural food corporation between two major informal groups whom they labeled “idealists” and “pragmatists” (p. 479). The reason causing this tension is that these two groups of managers have contradictory values around sustainability.

Hahn et al. (2015) conceptually asserted that tensions between individuals within and across organizations can be caused by divergent opinions and values toward sustainability. In particular, Smith and Lewis (2011) identified belonging tensions which occur when individuals’ values and identities belong to their referent groups. Similarly, Sharma and Bansal (2017) observed that “actors’ ontological positions, therefore, invoked actions that reinforced their position to tensions” (p. 361). In particular, Peng and Nisbett (1999) believed that fundamental cultural differences in ontology and epistemology at a philosophical

level lead to substantial cognitive differences in approaching opposing elements. In their study of divergent cultural approaches to contradictions, they found that the Chinese tended to take a dialectical, or compromise, approach that retains basic elements of opposing perspectives through a “middle way.” In contrast, the Westerners tended to view tensions more as contradictions. Here “the Chinese” refers to East Asians who are traditionally influenced by the ancient Chinese civilization (Li, 2012, p. 850), while the Westerners are from the western world, where countries such as the United States, Canada, those in the European Union (and the European Free Trade Association countries), Australia, and New Zealand are traditionally influenced by ancient Greek civilization (Hayford, 2009, p. 893).

Likewise, Chen (2002) suggested that “in many respects, Chinese and Western worldviews are philosophically opposed” (p. 183). To explain, there are two core epistemological systems in the West, namely, Aristotle’s “either/or” formal logic and Hegel’s dialectical logic of the “both/or” system (Li et al., 2012, p. 854). Characterized by this analytical view, Westerners tend to regard tensions as independent objects, thus denoting a “loosening” or “breaking apart” by polarizing contradictory perspectives to determine which fact or position is deemed to be correct (Chen, 2002, p. 183).

In contrast, “Chinese philosophical origins are deeply rooted in the ‘middle way’ teachings of such influential philosophers as Confucius and Lao Tzu (the founder of Taoism)” (Chen, 2002, p. 183). Confucian philosophy recommends *zhong he*, a concept based on middleway thinking. Literally, “harmony is the key in achieving prosperity”. “If *zhong he* is reached, writes Confucius in *The Book of Means*, heaven and earth will be in place, and all things will grow” (Chen, 2002, p. 183). Even today, Chinese culture continues to place a high value on the middle way. At the deepest level, the “middle way” is a “both/and” dialectical epistemology, which is distinct from the formal logic paradigm dominating Western traditions (Liu, 1974; Lloyd, 1990).

Based on the above rationale, it can be proposed that due to being influenced by different

cultural roots, Western and Chinese decision-makers may have contradictory understanding of competing dimensions.

Methodology

Research Philosophy and Methods

This entry was guided by an interpretivist philosophy and adopted a qualitative and abductive approach as the preferred research method as the results are based on managers' subjective experience, and their own interpretations and perceptions as representatives of their firms (Bryman & Bell, 2003; Creswell, 2013).

In order to develop novel insights into tensions, this study followed an abductive reasoning approach. Throughout constant movements back and forth between theory and empirical data (Wodak 2004), the abduction approach develops continuous dialogue between observation and the interpreter's preexisting understanding (Hatch and Yanow 2003) and, thus, is more likely to create a dynamic relationship between the existing theory of tensions and empirical data, ultimately providing more enriched perceptions of tensions in the sustainability research field.

Drawing from the traditions of qualitative research, this study utilizes semistructured in-depth interviews. For the present study, we employed semistructured in-depth interviews because, first, they offer freedom and flexibility to examine exploratory inquiries about tensions in sustainability in Chinese and NZ firms in business partnerships. As Yin (2010) claimed, semistructured interviews allow participants the freedom to express their views and perceptions in their own terms and provide the rigor and direction of questions especially developed for the research. In the present study, the researcher had a list of relevant questions known as an interview guide.

Research Context and Selection of Participants

This entry focuses on what tensions occur in sustainability between relatively large Chinese and New Zealand companies across various industries

and how these companies manage the tensions. Hence, we used purposeful sampling and snowballing techniques for identifying companies and potential participants (Mason, 2002; Miles & Huberman, 1994). This was also guided by some recent studies which explore tensions in sustainability within organizations. For example, Ozanne et al. (2016) applied purposeful sampling to select case organizations that were attempting to manage social, economic, and environmental dimensions of sustainability.

Based on the information provided by the New Zealand China Council (2015) and Statistics New Zealand via the Ministry of Business Innovation and Employment (2016), we found that the majority of Chinese and New Zealand firms in business partnerships are of a relatively large size. The next step was to ensure that selected companies have relatively mature sustainability strategies and implementations so that participating managers would be knowledgeable in the practice of sustainability. In doing so, we read relevant documents and archival records to find out if the selected firms have annual sustainability reports, and whether they provided information on sustainability activities on their websites and through social media. Then firms were approached by personal contacts through emails, LinkedIn, and Wechat.

In terms of selection of participants, three criteria needed to be met for this study. First, all the interviews were conducted with participants whose main responsibilities lie in management, senior management, and executive positions. The decision to interview people who are in management positions was also guided by the practice of the research area: In recent empirical studies of tensions in sustainability among organizations, the majority of data was collected through interviewing managers, senior managers, and CEOs (Carollo & Guerici, 2017; Ferns et al., 2017; Iivonen, 2018). Second, we also made sure that the selected participants are directly involved in managing the business partnerships between their firms and their related partner firms and thus able to provide richer and deeper information on tensions. Third, in order to increase the credibility of findings in this qualitative research, we also ensured that the informants come from a diverse

range of industries such as health and safety, aviation, dairy, IT and technology, and other areas. The informants also vary in years of experience in management, ranging from novices to those with more than 29 years of professional experience (Bryman & Bell, 2003; Sandelowski, 1995).

To further ensure that our sample included the most knowledgeable informants, we used a snowballing technique by asking the initial informants to recommend others within their firm or in their partner companies who could offer further insight regarding the research topic. Overall, Table 1 below shows the empirical material was based on interviews with 34 respondents from 11 Chinese and New Zealand firms.

Data Analysis

This study followed the thematic analysis process in the four steps suggested by Miles and Huberman (1994) and Braun and Clarke (2006). In particular, we used the Grounded Theory coding technique advised by Corbin and Strauss (1990) to generate all the themes and subthemes. As suggested by Waldman et al. (2019), qualitative research coding processes such as grounded theory and organizational discourse analysis provided a better way for us to explore tensions and how to manage them.

As a first step, we undertook data familiarization, whereby all the interviews were transcribed word for word. Transcripts were read and reread and notes taken to ensure data familiarization, and parts that seemed to be important through line-by-line reading were highlighted. Then, we went through data reduction, that is, coding and categorizing in order to make sense of the data through the constant comparative method to find similarities and differences. For coding, we followed the three stages suggested by Corbin and Strauss (1998): open coding, axial coding, and selective coding.

In the open coding, we went through the data, examining it, comparing one part with another, and beginning to make categorizations. As described by Corbin and Strauss (1990), open codes are a group of incidents with conceptual labels, which are assigned to each phrase, sentence, or paragraph. At this stage, we kept asking

what was happening in the data and focused on the events, actions, and interactions. For example, in order to identify the tensions, we were looking for indicator terms described by informants such as “problems,” “difficulty,” “challenging,” “tensions,” and “opposed/opposing” suggested by related empirical studies (Ferns et al., 2017; Slawinski & Bansal, 2015; Smith, 2014).

Once the conceptual codes began to accumulate, we started to categorize them by grouping them under more abstract explanatory terms as conceptual categories (Corbin & Strauss, 1998). In further analysis of the first-order codes, axial coding identified more theoretically informed second-order themes (Corbin & Strauss, 1990). In axial coding, the data was supposed to “determine the conditions that gave rise to the work, the context in which it was carried out, the action/interactions through which it occurred, and its consequences” (p. 13). Accordingly, we identified a set of codes that were developed more fully as we moved through each additional interview and company.

The third coding step is selective coding which is the final part where the main themes are drawn; it is “the process by which all categories are unified around a core category” (Corbin & Strauss, 1990, p. 14). In this process, coding was delimited to subcore categories which are related to the core category. The core category represents the central phenomenon of the study, and the subcore categories need to stand in relationship to the core category as conditions, action/interactional strategies, and/or consequences, where open, axial, and selective coding overlap (Corbin & Strauss, 1998). As a result of selective coding, categories and their subcore categories became more integrated and elaborate to build up the core category for this study; for details, see Appendix A.

Findings

In this section, the main tensions experienced, and the strategies used in managing the tensions, are discussed. Table 2 illustrates the findings that multiple tensions in four sustainability areas – triple bottom line, temporal, commercial, and

moral tensions, and spatial tensions – create more difficulty and challenges for these companies to manage simultaneously.

Identification of Multiple Tensions (IMT)

Financial Dominance of Triple Bottom-Line Tensions

First, with comments from 15 participants, we identified Triple Bottom Line (TBL) tensions between Chinese and New Zealand firms in business partnerships. As TBL requires firms to contribute to environmental, economic, and social performance (Elkington, 1997), the TBL tensions between Chinese and New Zealand firms in business partnerships thus can be understood as these firms having contradictory strategies in addressing environmental protection, economic prosperity, and social justice in their daily business activities. This finding reflects the strategic tensions which were mainly identified in recent studies from a conceptual perspective within firms (Hahn et al., 2018; Hahn et al., 2015). With comments from 11 participants at seven firms, the findings showed that Chinese firms tended to pursue financial growth, while their New Zealand partner firms tended to achieve financial returns and environmental or social objectives. For example, director A1 clearly reported such tensions:

What I would say is that our Chinese partner firm has a big focus on the financial performance. I think their main driver is to return a dividend for their shareholders whereas we are focusing on returning a dividend for our shareholders and also maintaining sustainable farming such as setting goals around animal treatment and wastewater management. (Director A1)

Similarly, one nonexecutive director B1 asserted:

Honestly, we do not worry about sustainability issues. To us it is just about looking at whether business activities can meet financial goals or not. Our Chinese directors do not understand the business; they only can look at budgets and if the New Zealand partner firm does not meet the monthly budget, then there is something wrong. We believe that our New Zealand partner will look after the environment such as protecting waterways and animal welfare. (Non-Executive Director B1)

Interestingly, the findings also indicated that, although some participants reflected that Chinese and New Zealand firms in business partnerships had tensions in addressing these environmental, financial, and social issues, the majority of tensions in their business partnerships are around commercial activities while how to deal with sustainability issues had not yet come up or had been relegated to an unimportant position. As evidence, one director at firm A stated:

I think it is quite early days for us and our Chinese partner to have some tensions in addressing environmental or social issues. As this partnership has lasted only about 2 years, the only tension we have come across was about economic goals. (Director A3)

Then this informant described the rationale for this, i.e., the main reason this partnership was established was because it is a win-win joint venture partnership for both firms. As he continued:

We could see the benefits of this joint venture partnership. The reality was our company was carrying a lot of debts. At this time, forming this partnership helped us out of financial difficulty and also realised our ambition to grow exports into the Chinese market. While on the other side, it is also beneficial for our Chinese partner firm, because they can get sustainable food from us. (Director A3)

Temporal Tensions

The second tension is temporal as Chinese and New Zealand firms in business partnerships confront strategies for addressing today's business success and tomorrow's business development and public welfare, based on 21 participants' sentiments.

Interestingly, the findings also showed the differences between Chinese and New Zealand firms in addressing sustainability issues from a temporal perspective. With comments from 17 participants at eight firms, the empirical analysis demonstrated that most New Zealand firms tended to have a sustainable business as well as being socially responsible, while their Chinese partner firms just wanted to achieve short-term business profits without thinking of long-term plans. For example, one senior manager at firm E clearly demonstrated this tension:

There are many short-term and long-term tensions in our business partnership. Our Chinese partner firm is like any company, which is driven by short-term profits and financial positions. They have targets and they have things to achieve for the financial year, so that drives them very heavily and it skews their decision-making. They will recommend to us and try to push us towards things that are commercially favourable for them. However, our firm on the other side probably will be more focusing on the long-term development. (Senior Manager E3)

This argument was also confirmed by another participant at firm E. According to this participant:

From my perspective, our Chinese partner firm does not play a long game. They play a short to medium-term game, because they do not think about what they are going to do next. However, we are looking at, for example, 25% to 30% less power consumption for the same output in our products. This has a big impact not only on business development but also for environmental protection, which means we can run some devices in cold temperatures with less carbon emissions. (Senior Manager E2)

The above two managers' comments indicated that, in comparison to the Chinese firm F, its New Zealand partner at firm E tended to contribute to developing business and managing public goods that are "nonexcludable and nonrivalrous such as water and air" (Slawinski & Bansal, 2015, p. 533).

Insignificant Commercial and Moral Tensions

Third, the empirical analysis showed that only five participants reported commercial and moral tensions in their business partnerships. For instance, the CEO of company C reported the tensions with their Chinese partner company D in shutting down one important factory:

We shut an important factory only late last year. In fact, the decision was made locally and it did have a bad impact as a large number of people lost jobs. Before the final decision was made, there were some debates between our leadership team and our partner company. The Chinese team wanted to keep it open for longer because they did not want to see many people lose jobs, but we wanted to shut it down, as it was no longer financially profitable. (Chief Executive Officer C1)

From this perspective, it can be seen that tensions arose between New Zealand company C and its

Chinese partner company D. While company C's action tended to be driven by commercial imperatives, company D cared more about moral responsibility by considering employee interests, and its potential impact on the local community. This finding is consistent with Hahn et al. (2016) who proposed that firms are faced with tensions in addressing instrumental and moral initiatives, thus highlighting firms confronting tensions "resting upon [a] different, contradicting foundation, the business case and the moral case, respectively" (p. 215).

Minor Spatial Tensions

With comments from ten participants at five firms, the empirical analysis also identified spatial tensions between Chinese and NZ companies in business partnerships. Based on participants' sentiments, spatial tension can be defined as "when Chinese and NZ firms do business with each other, they are faced with the challenge of either obeying China or NZ sustainability standards in addressing social and environmental issues." For example, the senior manager at firm O asserted:

Every country has different regulations. So New Zealand regulations are our backbone because that's where we make all the products. So every product in the factory needs to meet the New Zealand regulations. However, China has different standards to regulate healthy products, for example, it is legal in China to put 90% flour outside capsules with only 10% healthy ingredients. Therefore, our Chinese partner firm asked us to provide such products to Chinese customers, which causes tensions in our partnership. (Senior Manager O1)

The above manager's comment revealed spatial tensions in their business partnership, as China and NZ have different laws in regulating healthy products, raising tensions in addressing social responsibility. Similar tension was also identified in the partnership between company E and F.

Discovering Multiple Reasons Causing the Tensions (MRCT)

The empirical results indicated that reasons causing the tensions derive from individual,

organizational, and national levels. Accordingly, this study generated the subcore category of “multiple reasons causing the tensions” representing three conceptual categories of “individual-level reasoning: decision-makers confronting attitudes towards sustainability, ‘organisational-level reasoning’, and ‘national-level reasoning.’” The frequencies of the multiple reasons causing the tensions (MRCT) are illustrated in Table 3. Each category is explained in detail in the following three subsections with comments from informants and related literature.

Individual-Level Reasoning: Decision-makers Confronting Attitudes Toward Sustainability

On the individual level, the empirical analysis showed that managers at Chinese and NZ firms tended to have different values and norms regarding sustainability, which caused tensions in their business partnerships. This endorses the view mentioned in the literature that tensions in sustainability might arise for organizations when their decision-makers have divergent values and opinions regarding sustainability (Ashforth & Reingen, 2014; Besharov, 2014; Hahn et al., 2015; Maon et al., 2008). However, these studies only mentioned managers who either value one side of sustainability dimensions or the other, for example, managers who either value social or commercial sides instead of both (Smith & Besharov, 2019). Rather, the empirical analysis of this study illustrates managers’ “either/or” and “both/and” values toward the competing demands in sustainability. As one informant at company B commented:

Paradoxically, my experience is that tensions occurred in our business partnership because the Chinese directors do not understand the NZ... industry. They just do not talk about how to address sustainability issues, it is something that occurs at a lower level. What they only understand or the first thing in their mind is finance. I remembered once one of the key shareholders came out and said that the budget of our NZ partner firm is not good enough: this is the number that he wants. (Nonexecutive Director B1)

The above manager’s comment indicated that the Chinese decision-makers at their partner firm

represent what Ashforth and Reingen (2014) called “pragmatists” who endorsed financial viability much more strongly compared to “idealists.” This statement was also affirmed by another informant at firm A, director A1: “It took a while for the Chinese new management team to understand the complexities between business and environmental practice such as how grass grows and how animals grow.”

In comparison, the decision-makers at their NZ partner firm A tended to have a better understanding of the competing demands in sustainability. As he continued:

My view is that managers at our NZ partner firm can see their business returns are dependent upon nature and if it rains and the grass grows the stock won’t come, but if it’s sunny and the grass dries, the stock will come. They know that their business is at the mercy of the weather. In addition, they cared a lot about farmers’ interests, because they know if farmers are not happy, then they will not get enough stock. If there is no stock, then there are no profits. (Nonexecutive Director B1)

The above comments of participants demonstrated that tensions existed between companies A and B because Chinese decision-makers at firm A had a strong business mindset prioritizing financial performance over other sustainability performance without seeing their connections. In contrast, NZ decision-makers at firm B knew that it is important to implement sustainability, because addressing environmental or social aspects can help them generate financial returns.

Organizational-Level Reasoning

The findings of the empirical analysis revealed that two factors at the organizational level may trigger tensions related to sustainability in Chinese and NZ business partnerships. They involve contradictory organizational sustainability standards and regulations and opposed organizational economic goals, which are discussed accordingly in the following two subsections.

Contradictory Organizational Sustainability Standards and Regulations

Comments from 24 participants at nine companies suggested that different organizational sustainability standards

[illegible]

and regulations lead to tensions in their business partnerships. This finding is supported by prior studies which argued that tensions may occur when organizations have multiple and potentially contradictory values in sustainability practice (Bansal, 2003; Besharov, 2014). However, the empirical analysis also showed that Chinese companies do not seem to have rigid sustainability policies and regulations which are dominated by financial performance. In comparison, their NZ partner companies tended to have stricter sustainability policies. This caused the tensions in their business partnerships.

Evidently, some companies' A and B participants' comments suggested that their companies' sustainability policies and strategies are in opposition to each other, which triggered TBL tensions and temporal tensions in this business partnership. Four key informants reported that Chinese company B's policy has a strong focus on financial performance, which neglects other sustainability performance such as social and environmental policies. As announced by one informant:

What I would say is that our Chinese partner firm has a big focus on the financial performance of the company. I do not know whether they are particularly interested in the sustainability policies, and I do not think that really interests them. I think they are more interested in what directly affects their business. (Director A1)

The above statement was also echoed by another informant at Chinese partner company B, Director B2: "Our company policy involves strict rules to regulate financial performance which requires us to look at financial returns and assess them every single month." This strategy is in contrast to the policy of its NZ partner company.

Opposed Organizational Economic Goals Although TBL tensions were identified between Chinese and NZ companies in business partnerships, this kind of tension was dominated by financial tensions. Specifically, the empirical analysis showed that, being pressed to achieve certain financial goals, the Chinese and NZ firms in business partnerships may confront different

business strategies, which causes financial tensions in their business partnerships. This was most evident in the partnership between companies E and F. As senior manager E3 explained, "A lot of financial tensions in our business partnerships are driven through financial gains for both parties. The financial returns should not be the key pressure but they become the key pressure." Echoing this comment, another participant at company E stressed, due to the different size of the two markets, his company and their Chinese partner company applied different governance structures to obtain business profits that are beneficial for their companies, respectively, which gave rise to financial tensions in their business partnership. As this participant remarked:

I think tensions in our business partnerships are largely business driven, instead of culturally or nationalistically driven. If you think of the size of our organisation, hundreds of sites across NZ with a population of four million people. Our Chinese partner company is dealing with networks that have thousands of sites across a population of 1.5 billion people. So they have set up their business practices to manage that massive scale applied in China. (Senior Manager E4)

However, their Chinese partner company wanted to apply the same business strategies in their company, which caused tensions in this business partnership. As this manager continued:

And then they brought those business practices outside of China and wanted to apply them in other European countries such as NZ. But from our perspective, we do not need these big governance structures for such a small organisation. But when you take a step back you realise that it is difficult for our Chinese partner company to drop that business strategy and change it for us. Sometimes it can be a bit frustrating that it caused many tensions between the two parties. (Senior Manager E4)

National-Level Reasoning

Considering the findings are based on participants' perceptions, the present study found that spatial tensions were caused by two factors: different national sustainability regulations and national government interference. This is

explained along with the evidence of comments from respondents in the following two subsections.

Contradictory National Sustainability Regulations Comments of six participants from four companies suggested that different national standards in sustainability regulations resulted in spatial tensions in Chinese and NZ companies’ business partnerships such as different Chinese and NZ requirements in regulating health and safety issues, taxation, biosecurity rules, and product testing. This was most evident in the partnership between NZ company G and Chinese partner company H. A good example was provided in relation to regulating collagen products. According to one director at company G, Chinese law requires toxic ingredients to be evaluated through an animal testing regime first, which is contradictory to NZ’s rules:

This is an interesting example. All of our products can be sold in China once they are approved by Chinese authorities. I remembered there were some certain products that have to go through animal testing to check the level of toxicity by Chinese authorities. However, we do not endorse animal testing of our products like China. Our products are tested on ourselves first and then on humans in NZ. This is contradictory to the regulations of NZ and our company values. (Director G1)

This resulted in tensions in this business partnership that both parties needed to deal with. As this participant continued:

We said to our Chinese partner company that our company is not going to go through this testing process. Eventually, we had to come to some agreement with our Chinese partner company regarding this issue. Also, we had many discussions with the Chinese government; you can see that there was a contradiction between Chinese and NZ regulations that our company couldn’t accept, because it would be too damaging to our brand if we had to submit to animal testing. (Director G1)

Paradoxical Lens in Sustainability Tensions: Chinese and New Zealand Partnerships, Fig. 1 A holistic framework of knots of tensions in sustainability

Discussion

Based on the results of interview with 34 respondents, we sought to contribute framework for better illustrating the relationships in tensions in sustainability (see Fig. 1 for illustration).

In Phase 1, the framework suggests that an integration of multiple reasons from individual, organizational, and the national level raise sustainability tensions between Chinese and NZ firms in business partnerships. At the individual level, this framework indicates that TBL, temporal, commercial, and moral tensions can be caused by decision-makers' different attitudes and norms toward the competing sustainability demands (Ashforth & Reingen, 2014; Besharov, 2014; Hahn et al., 2015; Maon et al., 2008). In terms of organizational factors, this framework indicates that TBL, temporal, commercial, and moral tensions can be caused by different Chinese and NZ organizational sustainability regulations and standards (Besharov, 2014; Howard & Jaffee, 2013; Li, 2016; Slawinski & Bansal, 2012; Smith & Lewis, 2011). With regard to national factors, the framework illustrates the existence of spatial tensions which can be caused by two factors. First, spatial tensions can be caused by different Chinese and NZ national sustainability regulations (Hahn et al., 2015). Due to these multiple reasons, sustainability tensions between Chinese and NZ firms in business partnerships thus arise, as shown in Phase 2. Drawing from paradox theory (Schad et al., 2016), Phase 2 indicates that multiple sustainability tensions exist between Chinese and NZ companies in business partnerships, which are difficult and challenging for them to manage at the same time. According to the findings of this study, tensions in four sustainability areas were identified: TBL, temporal, commercial versus moral, and spatial tensions. This affirms the conceptual view that tensions exist in addressing divergent sustainability issues for companies (Hahn et al., 2015; Hahn et al., 2016). However, based on empirical findings, despite identification of multiple sustainability tensions, the framework (see white cycle in the middle of phase 2)

illustrates that these tensions have been put into unimportant positions or neglected by these companies as shown by "financial dominance of triple bottom line tensions," "no commercial and moral tensions," and "no spatial tensions," thus highlighting these companies' lack of awareness of the importance of these tensions. Moreover, this framework also illustrates the tied and nested relationships (signified by overlapping blue shadow) among multiple sustainability tensions, i.e., they partially overlap with each other across individual, organizational, and societal levels in an interwoven system. This reflects the holistic tenet from paradox theory, which accentuates the interrelatedness of multiple organizational tensions (Jarzabkowski et al., 2013) in that moving one competing demand will affect the whole system (Hampden-Turner, 1981), thus confirming their complexity (Smith & Lewis, 2011).

On the individual level, the results demonstrated that managers at Chinese and NZ firms tended to have different values and norms toward different sustainability dimensions, which may lead to TBL tensions, temporal tensions, and commercial and moral tensions in their business partnerships. This reflects the view mentioned in the literature that tensions in sustainability might arise for organizations when their decision-makers have divergent values and opinions regarding sustainability (Ashforth & Reingen, 2014; Besharov, 2014; Hahn et al., 2015; Maon et al., 2008). However, the empirical analysis showed the differences between Chinese and NZ managers' values and norms toward divergent sustainability dimensions. For example, the findings indicated that, despite being deeply influenced by the Chinese "middle way" in "both/and" dialectical epistemology, Chinese managers tend to hold "either/or" views by prioritizing economic performance over other sustainability demands without seeing their connections. Despite being influenced by Western "either/or" and "both/or" formal logic, NZ managers tend to see the necessity of practicing sustainability as they regard sustainability elements as complementary so that managing one dimension well will transform the others. This

finding does not support the view that, traditionally being influenced by Chinese and Western culture, Chinese managers tend to adopt “both/and” logic by seeing the connections between or among opposing aspects, while Western managers may use “either/or” logic by prioritizing one perspective over the other (Keller et al., 2018; Keller & Loewenstein, 2011; Keller et al., 2017). Based on this illustration, the following proposition thus can be made:

Proposition 1 Sustainability tensions between Chinese and NZ companies in business partnerships can be caused by decision-makers’ different attitudes and norms toward the competing sustainability demands. However, these differences may not be influenced by traditional Chinese and Western cultural roots.

With regard to organizational factors, while a growing amount of studies pointed out that organizations operating in global markets may have multiple and potentially contradictory values in sustainability practice (Besharov, 2014; Howard & Jaffee, 2013; Li, 2016; Slawinski & Bansal, 2012; Smith & Lewis, 2011), these studies did not elaborate that different organizational sustainability regulations may cause tensions between firms. Rather, in this study, the researchers found that different organizational sustainability standards and regulations result in tensions between Chinese and NZ firms in business partnerships. In terms of organizational factors, the findings of the empirical analysis elaborated two related factors that may trigger sustainability tensions between Chinese and NZ companies. First, different organizational sustainability standards and regulations give rise to tensions such as TBL tensions, temporal tensions, and commercial and moral tensions in their business partnerships. This finding endorsed the argument that tensions may occur when organizations have multiple and potentially contradictory values in sustainability practice (Bansal, 2003; Besharov, 2014). However, the present study also pointed out the differences

between Chinese and NZ companies’ sustainability regulations and standards.

Proposition 2 Sustainability tensions between Chinese and NZ companies in business partnerships can be caused by different organizational sustainability regulations and standards. However, instead of just focusing on developing organizational financial regulations and policies, it is imperative for Chinese companies to improve their organizational sustainability regulations and standards through learning from their NZ partner companies.

Further, while the multiple tensions identified in this research are not completely new to sustainability research, the empirical categorizations of four areas of tension overlap into an interwoven system. This is mainly because these tensions go across individual, organizational, and societal levels. This reflects the holistic tenet from paradox theory, which accentuates the interrelatedness of multiple organizational tensions (Jarzabkowski et al., 2013) in that moving one competing demand will affect the whole system (Hampden-Turner, 1981), thus confirming their complexity (Smith & Lewis, 2011). For instance, the TBL tensions identified in addressing economic performance and environmental/social performance validate the view that some companies seemed to concentrate more or just on how to achieve financial returns that are beneficial for shareholders and the company itself, while their partner companies tended to achieve financial and environmental/social initiatives simultaneously that benefit their companies and society, which emphasizes that the tensions are connected across organizational and societal levels. In addition, the temporal tensions were identified in that the Chinese and NZ firms in business partnerships confront strategies in addressing today’s business success for companies’ interests and tomorrow’s business development and public welfare for both companies’ and societal benefits, which highlights that the tensions are intertwined across organizational and societal levels. Moreover, the commercial and

moral tensions identified in this study mean that some firms tended to be driven by commercial imperatives by pursuing financial returns that are beneficial for their organizations and shareholders, but their related partner companies were more likely to behave from a moral perspective, to ensure they are doing the right things for the related stakeholders such as staff, and consumers, which highlights that the tensions reach across individual, organizational, and societal levels. Furthermore, spatial tensions emphasize that Chinese and NZ companies confront different opinions on whether to obey China or NZ's sustainability regulations and standards, for example, in addressing environmental and social issues, which highlights the tensions between organizational and societal levels. Through these illustrations, it thus can be argued that these firms are faced with multiple and complex tensions in addressing sustainability issues. This research thus generates the following proposition:

Proposition 3 The Chinese and NZ companies in business partnerships are faced with multiple sustainability tensions which partially overlap with each other and connect across individual, organizational, and societal levels in an interwoven system, which endorses their tangled and nested relationships through a paradoxical lens.

Theoretical and Managerial Implications

Theoretical Contribution

First, this study contributes to the methodological implications of tensions in sustainability research. As Fairhurst and Putnam (2018) stated, new developments in qualitative research methods in relation to data analysis methods such as using coding processes in grounded theory and organizational discourse analysis offer a novel way for researchers to better examine tensions in organizations. Alternatively, this research heeds this call by using the coding process of grounded theory suggested by Corbin and Strauss (1998), which helped to identify tensions by situating them in a

specific context of Chinese and NZ business partnerships through developing sets of categories. In addition, this coding process helps the researcher to explore the complex relationships among multiple sustainability tensions that link directly to the development of knots through how tensions become intertwined and nested in one another (Sheep et al., 2017). Further, this coding process also helped the researcher to explore the strategies these companies use in managing the tensions and their potential outcomes (Putnam et al., 2016).

Second, the present study adds value to the existing literature exploring the reasons for the tensions in sustainability in a detailed analysis. Most sustainability scholars tended to identify reasons causing tensions within firms by mainly focusing on the individual level (Ashforth & Reingen, 2014; Besharov, 2014; Hahn et al., 2015; Maon et al., 2008) and organizational level (Besharov, 2014; Li, 2016; Smith & Lewis, 2011). However, this research extended these works by showing multiple reasons causing sustainability tensions from individual, organizational, and national levels. At individual level, some prior studies suggested that, as being deeply influenced by different cultural roots, belonging tensions can be caused where Chinese managers tend to adopt "both/and" logic by seeing the connections between or among opposing aspects, while Western managers may use "either/or" logic by prioritizing one perspective over the other (Keller & Loewenstein, 2011; Keller et al., 2017). However, such stereotypical descriptions might be oversimplified (Schad et al., 2016) and lack any empirical study to investigate this perspective in other fields such as sustainability (Waldman et al., 2019). This research questions this idea by revealing that the Chinese and NZ managers tend to have contradictory values and norms toward the opposing sustainability demands which can cause TBL, temporal, commercial, and moral tensions. However, their opposing values in sustainability may not be influenced by Chinese and NZ cultural roots of "both/and" and "either/or" logic, respectively.

In terms of organizational factors, prior research generally suggested that tensions can be caused by different organizations having contradictory identities regarding sustainability and its practice (Besharov, 2014; Howard & Jaffee, 2013; Li, 2016; Slawinski & Bansal, 2012; Smith & Lewis, 2011). However, this research found that TBL, temporal, commercial, and moral tensions can be caused by different Chinese and NZ organizational sustainability regulations and standards where most Chinese companies do not have rigid sustainability policies and regulations compared to their NZ partner companies. With regard to national factors, the present study demonstrated that spatial tensions can be caused by different Chinese and NZ national sustainability regulations and government interference, which may prevent these companies from operating sustainability initiatives, thus negatively affecting the achievement of holistic sustainability.

Managerial Implications

First, this research can help the practitioners to recognize that they face multiple sustainability tensions to manage at the same time which partially overlap across individual, organizational, and societal levels in a knotted and nested relationship. This reminds the practitioners that it is difficult and challenging for them to manage the sustainability tensions simultaneously, because moving one competing demand may affect another one. Further, based on the empirical analysis of the present study, compared to NZ companies, Chinese partner companies do not have rigid sustainability policies and regulations which are dominated by financial performance, thus causing tensions in their business partnerships. From this perspective, this research thus argues that, although Chinese companies have started to be aware of the importance of sustainability implementation, they need to learn from NZ companies how to achieve financial and nonfinancial sustainability through improving their organizational sustainability regulations and standards.

Second, this study informs practitioners that the tensions between Chinese and NZ firms in

business partnerships are caused by an integration of multiple reasons from individual, organizational, and national levels. In particular, the results highlighted that Chinese and NZ managers' different values and norms can give rise to sustainability tensions which may not be influenced by their traditional cultural roots. Perhaps Chinese practitioners should be trained in and educated about the traditional Chinese philosophy of the "middle way" thinking, which might help them to generate "both/and" logic that is beneficial for managing opposing sustainability demands at the same time. Moreover, this research advises practitioners that sometimes the powerful national level factors may prevent these companies from practicing sustainability initiatives, which may have a negative impact on achieving holistic sustainability. Practitioners could work with national governments in order to develop better relationships with them through enhancing communication to make it easier for them to practice more sustainability initiatives.

Summary

In conclusion, this chapter empirically investigated tensions in sustainability between Chinese and New Zealand firms in business partnerships through showing how tensions arise and are managed. In doing so, 33 in-depth individual interviews alongside one informal group discussion were carried out at 16 relatively large Chinese and New Zealand firms in business partnerships, with staff who are in management, senior management, and executive positions, and directly managing their business partnerships. This research manifests that Chinese and New Zealand firms in business partnership are faced with complex and multiple sustainability tensions which are partially overlapped across individual, organizational, and societal levels. These tensions are caused by an integration of multiple reasons from individual, organizational, and national levels.

Appendix A1: Conceptual Codes and Categories

Open coding	Axial coding	Selective coding	
Conceptual codes	Conceptual categories	Subcore categories	Core category
Chinese firms: economic performance versus NZ partner firms: economic and environmental/social performance	Financial Dominance of Triple Bottom Line Tensions	Identification of Multiple Tensions (IMT)	Mastery of Tensions in Sustainability (MTS)
NZ firms: economic performance versus Chinese partner firms: economic and environmental/social performance			
Financial tensions dominant, addressing sustainability issues becomes secondary			
Chinese firms: today’s business success versus NZ partner firms: tomorrow’s business development and public welfare	Temporal tensions		
NZ firms: today’s business success versus Chinese partner firms: tomorrow’s business development and public welfare			
Commercial imperatives versus moral imperatives			
Hardly any commercial and moral tensions as both parties behave ethically according to the law			
Adopting Chinese law in regulating social and environmental issues versus utilizing NZ’s law in regulating social and environmental issues	Minor spatial tensions		
No statement of spatial tensions as both parties just need to make sure their business activities obey the local regulations			
Chinese decision-makers’ “either/or” attitudes toward sustainability versus NZ decision-makers’ “both/and” attitudes toward sustainability	Individual-level reasoning: decision-makers confronting attitudes toward sustainability	Multiple Reasons Causing the Tensions (MRCT)	
NZ decision-makers’ “either/or” attitudes toward sustainability versus Chinese decision-makers’ “both/and” attitudes toward sustainability			
Contradictory organizational sustainability standards and regulations			
Opposed organizational economic goals			
Contradictory national sustainability standards	National-level reasoning		
National government interference

Introduction

Climate change is one of the defining problems of the twenty-first century. Indeed, this generation

has witnessed the defining episodes with unprecedented scale of catastrophic events that range from unpredictable weather patterns threatening food production to sea level rise that aggravates the risk of flood disasters (Tikkanen 2019). Though the human species is highly adaptive in nature as shown in the earlier phase of global warming in the twentieth century, the recent pace and extent of global warming is outdoing our coping capacity. Thus, if immediate actions are not taken to mitigate the trend, future adaptation plan to the impacts may become unrealistic and very costly (Streck et al. 2016; Tikkanen 2019).

Governments across the world, for the first time showed concern and set the tune for the stabilization of the concentration of greenhouse gases (GHG) with the adoption of an international treaty, the United Nations Framework Convention on Climate Change (UNFCCC) in May 1992. Efforts to ensure that the purpose of UNFCCC is achieved had delivered major milestones that include the adoption of the Bali Action Plan (2007), the Copenhagen Accord (2009), the Cancún agreements (2010), and the Durban Platform for Enhanced Action (2012) (UNFCCC 2015). However, the urgency of the need for an action was acknowledged by the historic 21st Conference of the Parties (COP21) of the annual UNFCCC held in Paris, France, in December 2015. The adoption and swift entry into force of the Paris agreement was indeed unprecedented (Denchak 2018; UNFCCC 2015). At the conference, which is also known as the climate change conference, 195 negotiating Parties expressed their commitment to take action to limit the global temperature increase to well below 2 °C while pursuing efforts to keep it within 1.5 °C above preindustrial level. The adoption of the Paris agreement signals the shift of the global economy away from fossil fuel and the beginning of a global transition to a net zero carbon economy. The international treaty, which was named after the host city, Paris, is primarily set out to improve on the lapses in the Kyoto protocol and other previous international agreements that are founded on limiting the emission of GHG (UNFCCC 2018).

History

The Paris Climate Agreement is the brainchild of over two decades of international climate dialog brought about through the launching of the UNFCCC at the United Nations Conference on Environment and Development (UNCED), also known as the Rio de Janeiro Earth Summit in 1992 in Brazil. Being only one of several international environmental treaties adopted at the Earth Summit, UNFCCC has a long-term objective of preventing anthropogenic interference with the climate system. Thus, since the launching, the UNFCCC, through its annual Conference of Parties, has become the heart of evolving global climate actions (UNFCCC 2015).

Having identified the urgent need to strengthen efforts on emission reduction in line with the UNFCCC goal, Parties convened at COP3 in Kyoto, Japan, on December 11, 1997, to commit to the Kyoto Protocol which became effective on February 16, 2005, with the first commitment period lasting from 2008 to 2012. The protocol acknowledges the different capabilities of individual countries to address the climate change challenges and thus is built on the “principle of common but differentiated responsibilities” which puts the responsibility of global emissions reduction on the developed nation based on their economic power and the fact that they are historically responsible for the present level of global emissions (Espinosa 2018; Clemenccon 2016). This treaty was however, generally regarded ineffective since two most important carbon dioxide emitters, China and USA, were not Parties while Canada withdrew from the protocol in 2012. Also, even though all 36 developed countries that participated in the Kyoto protocol reduced their GHG emission during the commitment period, the overall global emission grew by 32% from 1990 to 2010 (UNFCCC 2015; Stavins and Stowe 2016).

As it had become obvious that the Kyoto protocol is hardly achieving the anticipated progress, at the 13th Conference of the Parties held in Bali, Indonesia, in December 2007, parties to the UNFCCC agreed to combine efforts to address global climate change challenges and to come up

with a robust international treaty that will operate sequel to the 2012 Kyoto protocol regime. The COP13 session led to the adoption of the Bali Road map that set a two-year negotiation process in progress to be concluded in 2009 at the 15th Conference of the Parties in Copenhagen (UNFCCC 2015; Tikkanen 2019). However, when over 100 world leaders gathered in Copenhagen, agreement could not be reached, but the Copenhagen Accord successfully set a goal on keeping global temperature increase within 2 °C and developed plans to mobilize \$100 billion annually by 2020 to support the developing countries and call for a new Green Climate Fund (GCF) to be established. At the COP16 held in Cancun in 2010, Parties established the Green Climate Fund administered by the GCF Board as a mechanism to finance projects, programs, policies, and other activities in party states that are less developed (UNFCCC 2015).

However, because of the inadequacies evident in the first commitment period of the Kyoto protocol, parties reconvened at the 18th Conference of the Parties (COP18) in Doha, Qatar, in 2012 and agreed on a second commitment period of 2012–2020 to the Kyoto protocol. Delegates also reaffirmed their commitment to the agreement of COP17 held in Durban, South Africa, in 2011 to come up with a new, comprehensive universal climate treaty by the year 2015 that will be legally binding and require action from all countries whether major or minor GHG emitter (Clemencon 2016; Tikkanen 2019).

On the path leading up to the landmark Paris Agreement, the United Nations had mandated that each country should develop and submit a plan termed “Intended Nationally Determined Contributions (INDCs)” detailing measures and effort they intend to implement to reduce GHG emission locally. Interestingly by 10 December 2015, 185 countries had already submitted their INDcs indicating their commitment to reduce their GHG emissions by either 2025 or 2030. Thus, on 12 December 2015, parties convened again at the 21st Conference of Parties to adopt the Paris Agreement (Denchak 2018; Rei et al. 2017). This landmark international treaty employs a

hybridization of the “top-down” approach of the Kyoto protocol and the “bottom-up” Copenhagen and Cancun approach. The hybrid legal nature of the Paris agreement made it quite easy for State parties to ratify, and by 4 November 2016, it had entered into force much earlier than anticipated. As of 2017, Nicaragua and Syria were the only sovereign nations that had not signed the Paris Agreement; those were also signals that the USA could pull out of the treaty by the end of 2020. By January 2020, of the 197 Parties to the Convention, 195 have signed while 187 have ratified the Paris Climate Agreement (UNFCCC 2015).

Objectives and Essential Elements of the Agreement

The overarching long-term goal of the Paris Climate Agreement as delineated in Article 2 according to UNFCCC (2018) and Espinosa (2018) is to reduce global warming and facilitate the implementation of the UNFCC through:

- (a) Limiting the global average temperature to well below 2 °C above preindustrial level while making effort to limit the increase to 1.5 °C.
- (b) The treaty also seeks to increase the adaptive capacity of State parties to adverse climate change impacts and stimulate climate resilience and low emission technology such that food security is not put at risk.
- (c) It further intends to secure a consistent flow of funds to facilitate low GHG emission and climate resilience.

These global goals provide a clear long-term path of travel to both governmental and corporate actors in finding a harmony between the climate systems, economic activities, and greenhouse gas emissions. This goal is intended to be achieved by peaking global GHG emission at the earliest possible time by 2020 and subsequently diminishing it along the years to reach a stability between anthropogenic GHG emissions by sources and removal by sinks towards the latter half of the

twenty-first century. Based on recent science, limiting the increase in global temperature to 1.5 °C above preindustrial level requires that net zero emission must be achieved by the year 2050 (UNFCCC 2018).

The Paris agreement is a vehicle for transition to climate neutrality, thus to drive action toward the realization of the goals of the Paris Agreement and the general outcome of the COP21; certain crucial elements are identified as being essential. These elements are highlighted in UNFCCC (2018):

- (a) Mitigation: To facilitate the realization of the objectives of the Paris agreement through reducing emissions fast enough to achieve the target temperature, Parties handed in detailed national plans for carbon emissions reductions, the Nationally Determined Contributions (NDCs). Article 6 generally profiles cooperative approaches for achieving NDCs. For example, paragraphs 6.2 and 6.3 outline a framework for International Transfer of Mitigation Outcomes (ITMOs) and linkage of emission trading system while paragraphs 6.4 and 6.7 provide a framework for Parties to contribute to emission reduction and promote sustainable development which is now informally termed “Sustainable Development Mechanism” (SDM) among Parties.
- (b) A transparency system and global stock-take: To ensure accountability for climate action and as established in Article 14, Parties committed to convening every 5 years starting from 2023 to review and evaluate their individual and mutual NDCs. This is to determine whether the NDCs are measuring up against the short-term goal of peaking global GHG emissions and plans to update their NDCs on the path to achieving the long-term goal of net zero emission. Article 13 of the Agreement describes an “enhanced transparency framework for action and support” which requires coordinated monitoring, reporting, and verification (MRV). Thus, even though parties are not legally bound by the NDCs, they are legally required to allow their climate action plans to be tracked by experts to evaluate progress toward individual Party’s NDCs and determine how best to bolster their ambition.
- (c) Adaptation: Parties are also committed to cooperate to strengthen countries’ ability to deal with climate impacts and provide support to the least developed countries to facilitate adaptation. Thus, Article 7 of the Paris Agreement includes, along with mitigation, parallel collective long-term adaptation goals which are built on improving adaptive capacity, strengthening resilience, and minimizing vulnerability.
- (d) Loss and damage: In order to strengthen regional ability to recover from adverse climate impacts, parties acknowledged the important need for addressing loss and damages resulting from climate change. Therefore, parties commit to collaborate to facilitate understanding and action to provide support in the form of early warning systems, emergency preparedness, and risk insurance as provided in Article 8 of the Agreement. This is pertinent, because much of the most deleterious effects of climate change may occur sooner than anticipated or may be more severe in impact and difficult to cope with.
- (e) Support: Articles 9, 10, and 11 of the Agreement reiterate the need for the developed nations to support developing ones in their effort to build a climate resilient future. The European Union and other parties from the global north also committed to provide continuous supports including finance to their global south counterparts to foster climate action that will minimize emissions and strengthen climate resilience.

Summary

The landmark Paris agreement is built on the foundation of the United Nations Framework Convention on Climate Change (UNFCCC) and the Copenhagen and Cancun Agreements to

combat climate change and reinforce global actions and investments for a low carbon future. This is intended to be achieved by limiting global temperature increase to well below 2 °C pre-industrial levels and to pursue efforts to keep the temperature increase to within 1.5 °C. An important strength of the Agreement is in its requirement for Parties to develop individual “Nationally Determined contributions” (NDCs) and submit regular reports on emissions that form basis for a global stock-take every 5 years to evaluate collective progress toward reaching the goal of the Agreement.

Definition

The term Participatory Development originates from international development practice and was established to give greater opportunities to have a voice for those who were intended to benefit from development projects. In the context of Participatory Development, the World Bank defines participation as “a process by which people—especially disadvantaged people—can exercise influence over policy formulation, design alternatives, investment choices, management, and monitoring of development interventions in their communities” (Bhatnagar and Williams 1992, p. 7). The Development Assistance Committee of the Organisation for

Economic Co-operation and Development (OECD) defines Participatory Development as “a process by which people take an active and influential hand in shaping decisions that affect their lives” (OECD 1997, p. 22). This means that Participatory Development refers to inclusion of those benefitting from a development project or process to initiate change. The term is now used in a broader sense for projects or processes of sustainable development involving local communities in both the Global North and South (Bell and Morse 2018).

Introduction

For several decades sustainability and sustainable development has been a key issue in the discourse on development (Campbell and Vainio-Mattila 2003; World Commission on Environment and Development, WCED 1987). In view of current societal challenges such as climate change, it is increasingly important to involve individuals and organizations in decision-making, for example regarding sustainable development, resource use, or climate adaptation measures. Participation is a way to achieve this. The concept of Participatory Development is not strictly defined and is not uncontested. The terms participation and Participatory Development are often used interchangeably. As the latter term is open to interpretation, it is useful to give a more clear-cut description of its meaning (Cornwall 2008; Mansuri and Rao 2013). Participatory Development refers to a process in which local actors or stakeholders have a say in development projects and are able to influence processes or projects which affect them (Sabbi 2017).

Origins of Participatory Development

Participatory Development originated as “popular participation” in international rural development projects in the 1970s (Vengroff 1974) and 1980s, for example with Robert Chambers’ initiative of “putting the last first,” which aimed at involving

the beneficiaries of rural development projects in decision-making about their own future (Chambers 1983). Chambers (1983) developed influential approaches such as Rapid Rural Appraisal. Later, Participatory Rural Appraisal (Chambers 1994) and Participatory Learning and Action (PLA; Chambers 2008) were set up, practical research strategies that placed increasing emphasis on co-operative learning. These approaches formed the foundation for subsequent participation work (Chambers 1983; Cornwall and Scoones 2022). In the 1990s, institutions and development agencies picked up the idea of Participatory Development, for example the World Bank (World Bank 1996; Mansouri and Rao 2013), the United Nations Food and Agriculture Organization (Ramirez and Fernandez 2007), the United Nations Development Programme (Telleria 2021), and the OECD (OECD 1995). As Participatory Development entered the mainstream, the term evolved into a popular catchall phrase and buzzword (Schnable et al. 2021), and it became more and more imperative to incorporate participatory approaches into projects and activities (Kanji and Greenwood 2001).

However, critical evaluations of participatory approaches on a project basis show that there is a gap between theory and practice of Participatory Development (Cornwall 2008). This is because implementation often falls short of the original transformative goals of Participatory Development (e.g., Hickey and Mohan 2004; Ika and Hodgson 2014; Telleria 2021).

The overuse of the term resulted in participation being reduced to an administrative ticking-off routine, where counting participants received more attention than inviting people to have an influence (Bell and Morse 2018; Cornwall 2022). Criticism also addressed the ongoing dominance of the position of external experts in development activities in the Global South, especially because Participatory Development did not result in expected impacts regarding governance and poverty reduction in many projects (Sabbi 2021). Some of the difficulties in achieving the expected impacts might be related to project management issues, as development projects are complex and

Participatory Development, Fig. 1 Summary of trends, origin, and evolution of the concept of Participatory Development. (Based on Bell and Morse 2018; Cornwall 2008; Howard and Wheeler 2015; Kanji and Greenwood 2001)

project teams often need to collaborate at a distance (Ika and Hodgson 2014; Zaher et al. 2021). Nevertheless, in addition to critical assessments there is also evidence for the benefits of Participatory Development outweighing the downsides (Bell and Morse 2018; Uphoff 2002). An overview of the origins and development of the concept of Participatory Development is given in Fig. 1.

Participants and Concepts

Participatory Development can be explained by looking at actors and concepts of participation (Campbell and Vainio-Mattila 2003). Actors and institutions are key elements of Participatory Development (Sabbi 2017). Therefore, it is useful to specify what this frequently used term actually means to different actors (Cornwall 2008). First,

the actors of Participatory Development are described and then an overview of selected relevant concepts of Participatory Development is provided.

A participant can be defined as “someone who participates” (Merriam-Webster Dictionary 2022a), that is, someone who takes part in a project. Often the term participant implies an active form of involvement; participants actively create and have ownership of their projects (Campbell and Vainio-Mattila 2003; Cornwall 2000). A stakeholder is “one that has a stake” and “who is involved or affected by. . .” a project (Merriam-Webster Dictionary 2022b). Over the years, authors in the field of Participatory Development have referred to participants as recipients, beneficiaries, stakeholders, and actors or partners (Campbell and Vainio-Mattila 2003; Cornwall 2000). These terms have different connotations and reflect the changing roles of participants,

depending on the extent to which involvement turns into influence of participants. Groups are usually heterogeneous and therefore participants have different perspectives. Already in the early days of Participatory Development, Cohen and Uphoff (1980) pointed out that “the rural poor” are not a homogeneous group, as they differ regarding, for example, occupation, land-ownership status, gender, and religion, and that these factors influence poverty for these people.

Heterogeneity of different views and perspectives is also reflected in different typologies of participation. Tufte and Mefalopulos (2009) state that there are two important perspectives to participation, (1) the institutional perspective, where participation supports the process to reach a pre-defined goal for the community addressed with the intervention, and (2) the social movement perspective, where participation is seen as a process to empower people offering possibilities for sustainable development (see Fig. 2). It is not a question of adhering to either of the two perspectives; both perspectives are relevant. Depending on perspective and typology of participation, the extent to which participants can influence processes may vary (Cornwall 2008).

Cornwall (2008) reviews different concepts of participation with respect to their applicability in

development practice. An early concept among the reviewed concepts is Arnstein’s ladder of participation (Arnstein 1969). This early concept contains two non-participatory categories (referred to as “therapy” and “manipulation”), where participants have no power, and six increasingly participatory categories. The latter start with three categories, which attribute some influence to the participants (placation, information, and consultation of citizens), and are followed by three further categories, in which power is increasingly taken over by participants (partnership, delegated power, and citizen control). Another reviewed concept is White’s typology of interests elucidating different interests of the stakeholders in different forms of participation (White 1996). Both concepts are normative, that is, describing “good” and “bad” forms of participation. The International Association for Public Participation provides a spectrum of five forms of participation with one passive and four active levels of participation (IAPP 2018). The IAPP spectrum represents a more gradual sequence of approaches comprising a passive level of participation (information of participants) and four active levels of participation with increasing empowerment of citizens (consultation, involvement, collaboration, and empowerment). Some authors prefer to

Participatory Development,
Fig. 2 Two perspectives on Participatory Development. (Based on Kanji and Greenwood 2001 and Tufte and Mefalopulos 2009)

use the IAPP five-stage system, as it is more inclusive and less normative (Akerboom and Craig 2022; Cornwall 2008).

Challenges and Trends

Participatory Development is a contested term and there is an ongoing need to specify clearly which concept of participation is applied, and which participants are involved and how (Kanji and Greenwood 2001). Challenges and trends in the field of Participatory Development can be attributed to three key discourses: (1) on the relationship between theory and practice, (2) on the co-creation of knowledge, and (3) on the role of external experts in Participatory Development (Campbell and Vainio-Mattila 2003).

In debates related to discourse (1) about the role of participants' experiences as a basis for the analysis, authors emphasize the importance of practical experiences, stating that theory and practice are integrated and cannot be separated (Campbell and Vainio-Mattila 2003). Discourse (2) is linked to the fact that in Participatory Development processes, different participants produce knowledge in social interaction. The knowledge involved belongs to two categories: expert knowledge (e.g., academic knowledge of advisors or external experts) and local or traditional knowledge of citizens or communities (Fouksman et al. 2022). Power imbalances influence the use and integration of different types of knowledge (external or expert knowledge versus local, practical, or traditional knowledge). Local knowledge provides valuable links to local context and is an indispensable complement to expert knowledge. It represents a vital resource for the implementation of development projects in the actual local contexts with different values (Uphoff 2002). To better integrate local knowledge, facilitators should aim at creating a co-learning environment valuing local knowledge (Kanji and Greenwood 2001). The third discourse (3) on unbalanced power refers to the role of external experts and reflects the relationship of participants and experts. Even though a mind-shift has taken place and relationships that are more equal are

replacing the old donor-to-passive-recipient approach, roles of experts and participants require ongoing attention to make sure that participants are able to influence processes (Campbell and Vainio-Mattila 2003).

In all three key discourses, the identification of stakeholders and their representativeness plays a central role (Bell and Morse 2018; Cornwall 2008). It is not possible to involve everybody, as groups are heterogeneous and dynamic. In addition, exclusion of certain groups through organizational settings is an issue requiring attention (e.g., difficulties for women in participating if meeting times coincide with family tasks; Cornwall 2000) and self-exclusion (if certain groups decide not to respond; Cornwall 2008). Exclusion of groups can lead to participation-fatigue, that is, if participants have been invited too often and are tired of participating, but this can be counteracted by making sure that participants can influence choices that matter. Not only do development projects navigate in a context of power imbalances but also participation itself is a field of power imbalances. As stated earlier, participants in development projects might not be representative and rather form part of privileged rather than marginalized groups. Often it is observed that participants in Participatory Development projects are not a representative subgroup of society, but have a higher degree of education and a higher social status and are more likely to be male than female (Ransom et al. 2021). This means that it is important to be mindful of these imbalances and of the political dimension of participation.

A key trend is the ongoing "re-export" of the concept of Participatory Development from the Global South to the Global North (Bell and Morse 2018), with funding institutions from the Global South entering the scene (Ika et al. 2020). Another important trend is the growing accessibility of information and the increasing use of the Internet and information and communication technologies. Access to information is a prerequisite to positive learning environments. The increased availability of electronic communication technologies can support learning in Participatory Development projects (Uphoff

2002). It is expected that these new technologies have the potential to enable more participation (Schwittay and Braund 2019). However, it is important to make use of these technologies in an inclusive and truly participatory way.

Participatory Development and Global Sustainable Development

Sustainability entered the development discourse in the 1980s (WCED 1987; Campbell and Vainio-Mattila 2003). To some extent, in the period from 2000 to 2015, the Millennium Development Goal (MDG) processes already increased the need for participatory approaches; however, often it turned out that marginalized groups were difficult to reach (Howard and Wheeler 2015). Since 2015, when the Sustainable Development Goals (SDGs) replaced the MDGs, there has been an even stronger emphasis on the need for Participatory Development approaches (Howard and Wheeler 2015). Participation is of key importance in the context of global sustainable development and the Sustainable Development Goals (SDGs). The link is especially significant to the so-called systemic SDGs, that is, those contributing to creating a system, an environment in which sustainable development is implemented. SDG 16 (Peace, justice, and strong institutions) focuses on facilitating peaceful inclusive societies free of insecurities and conflict (Leal Filho et al. 2021a). SDG 17 (Revitalize the global partnership for sustainable development) addresses the relationships between people, as people need to initiate the change to sustainable development (Leal Filho et al. 2021b). This development goal implies a different strategy of development fostering a more equitable partnership between the Global South and North. The two systemic SDGs focus on supporting the implementation of SDG 1 to 15 through inclusive decision-making at all levels and by strengthening partnerships between different groups and actors (bridging, e.g., North–South, and national, sectoral, and cultural differences). The SDG process is meant to be inclusive (Howard and Wheeler 2015). The representation

of participants remains a challenge for Participatory Development in the context of global sustainable development. Likewise, situating global goals in local contexts is a challenge.

Summary

Participatory Development means including those who benefit from projects in decision-making. The concept originated from dissatisfaction with the former top-down approach to development. Key challenges in Participatory Development processes include the involvement of representative participants, the interactive co-creation of knowledge, and valuating of knowledge from both local actors and experts. Another challenge is the roles of actors and power imbalances between them.

Definition/Description

The Peak Oil is the maximum of oil production either globally, nationally, or of an oil reservoir. The model for predicting the time, at which the maximum of oil production will occur, was developed by M. K. Hubbert in the 1950s (Hubbert 1956). Base idea is that the ultimately recoverable resources of oil are known and that production rate follows a bell-shaped curve in which the area under the curve is the total amount of the exploitable resource.

Introduction

While renewable resources are either indefinite or can be recovered in human time scale (see ► “Energy-Renewable”), the supply of mineral resources and resources of fossil fuels are limited (BGR 2017). Increasing population and growing standard of living have led to a continuous rise of energy consumption (IEA 2019), mostly supplied by fossil fuels. Since exploitation rate of limited resources cannot be increased indefinitely, a maximum of production will be achieved, after which exploitation rate will decline, since further enhancement is not feasible due to depletion of the resource.

When the maximum of oil production is achieved globally and demand is further increasing, a sudden rise of oil price is expected (Campbell and Laherrère 1998). Sudden boosts of oil prices in the past, as for example, during the first oil crisis 1973–1974 and the second oil crisis 1978–1979, led to severe economic shocks worldwide (Baumeister and Kilian 2016). A global economic crisis is also discussed (Tverberg 2012), when global oil production cannot be enhanced further and no alternative energy is available (Campbell and Laherrère 1998).

Hubbert’s Prediction of the Peaking of Oil Production in the USA and Globally

Hubbert showed that the production rates of oil, natural gas, and coal increased exponentially between 1890 and 1950 in the USA (Hubbert 1956). He concluded that this growth rates cannot persist for long time since fossil resources are finite and physical limits would prevent indefinite growth (Hubbert 1956, p. 8). Basing on the following assumptions, he developed his model:

- The production of fossil fuels is controlled by availability of the resource.
- Resources are limited and the ultimately recoverable amount is a given quantity.
- The production of fossil fuels follows a bell-shaped curve, in which the area under the curve

is equal to the total amount of exploitable resource (Hubbert 1956; Tilton 2018).

For validation of his model, he analyzed production curves of the US states Ohio and Illinois. In Ohio a step increase of oil production was observed starting 1884. Three maxima were observed in the period 1890–1900, with the global maximum around 1896 (Hubbert 1956, p. 11). Afterwards a steady decline was stated but oil production continued on small level ongoing in the mid of the 1950s.

In Illinois the first peak was observed around 1910, a second peak, which was three times higher, occurred 1940. Hubbert explained the two peaks here with different technologies for detection of oil reservoirs: While at the beginning of the twentieth century “surface geology with meager outcrop data” was used for finding oil reservoirs, the later findings of oil reservoirs were achieved by using seismographic measurements (Hubbert 1956, pp. 11–12), which was a superior method. Further increase of oil production in Illinois was predicted due to use of water flooding in already known reservoirs and by exploitation of other geological formations in this state. Hubbert estimated a reserve of four billion barrel crude oil (1 barrel = 159 liter in case of oil trade).

Hubbert predicted also that the maximum of oil production in the USA would be achieved between 1965 and 1970 (Hubbert 1956, p. 23). The maximum of oil production in the USA was indeed observed in 1970 (EIA n.d.; BP 2019), which supported Hubbert’s theory. But in 2008 oil production in the USA started to increase again (BP n.d.) due to development of horizontal drilling and fracturing technology, which enabled the production of oil and gas from shales (US Department of Energy 2009) as can be seen in Fig. 1. Around 2016 the USA became the biggest oil producer, in 2018 the USA produced 669.4 million tons (Mt), more than Saudi Arabia (578.3 Mt) and the Russian Federation (563.3 Mt) (BP 2019).

A peak of global oil production was predicted by Hubbert for the time around 2000 (Hubbert 1956, Fig. 20). As can be seen in Fig. 1

Peak Oil, Fig. 1 Global oil production (upper figure) and oil production in the USA (lower figure) (Data taken from BP [n.d.](#), own work)

(left side) 1979 global oil production peaked and declined at begin of the 1980s, much earlier than predicted by Hubbert. One reason was the second oil crisis caused by the Iranian revolution which led with some delay to an increase of oil price (Baumeister and Kilian [2016](#)). Since 1986 oil production increased again, a small decline in 2009 was caused by decreasing oil consumption due to the economic crisis (Baumeister and Kilian [2016](#)). A global peaking of global oil production

has not yet been observed (BP [n.d.](#)). Since 2009 oil production has been increased continuously, in 2018 the global oil production was 94.7 million barrels per day, 4474.3 Mt in total.

Review of the Concept of Peak Oil

In the 1990s Campbell and Laherrère picked up the ideas of Hubbard using the bell-shaped model

and updated estimates for global oil reserves. Using data of global cumulative oil production and conservative estimations of global extractable reserves, they estimated that the maximum of oil production would occur within the first decade of the twenty-first century (Campbell and Laherrère 1998). That was in accordance with Barnes, who discussed 1993 the “Oil Mountain.” Assuming a peak production of 90 million barrels per day and ultimately recoverable resources of 2200 billion barrels, he also predicted the maximum oil production in the first decade of the twenty-first century (Barnes 1993). But Barnes also pointed out that, if unconventional oil would contribute another 2000 billion of barrels, with the given production rate of 90 million barrel per day reserves would last well into the twenty-second century (Barnes 1993). But the mobilization of unconventional oil would require a certain oil price, since its production is more expensive than of conventional oil. While the interest in Peak Oil discussion was high in the 1990s and in the first decade of the twenty-first century, interest declined in the last years (Bardi 2019).

The first question is if availability of a resource governs its production. In France and Germany, decreasing demand was identified as reason for the stop coal production, not the depletion of coal reservoirs (Wellmer and Scholz 2017).

The second question is if the determination of ultimately recoverable resources is possible. For some regions and countries, the determination of recoverable resources was achieved. The oil production in Norway for example can be described with a bell-shaped curve (Sinding-Larsen and Wellmer 2012). But prediction of global resources of oil is controversial (Campbell and Laherrère 1998). In 2019, for example, BP estimated 1729.7 billion barrels (244.1 billion tons) of oil as proven reserves (BP 2019) while the estimation of the IEA in 2018 was 1694 billion barrels (IEA 2018).

The third question is how the amount of ultimately recoverable resources depends on price of the commodity. If prices for a commodity increase, exploitation of resources, which are more difficult to exploit, will become economic (Holland 2013). “A higher price will produce a higher and more distant production peak” (Tilton 2018).

Also technical developments can lead to higher exploitation of known reservoirs (Barnes 1993), and production of “unconventional oil” will increase the amount of ultimately recoverable oil (Barnes 1993). According to IEA, “Unconventional oil includes extra-heavy oil, natural bitumen (oil sands), kerogen oil, gas-to-liquids (GTL), coal-to-liquids (CTL)” (IEA 2011).

Recent Developments Affecting Oil Production

The development of technologies in the USA for shale gas and oil production increased the amount of recoverable resources significantly (Nunez 2013). The U.S. Department of Energy identified three factors, which made unconventional fracking feasible and economic: “(1) advances in horizontal drilling, (2) advances in hydraulic fracturing, and, perhaps most importantly, (3) rapid increases in natural gas prices in the last several years as a result of significant supply and demand pressures” (U.S. Department of Energy 2009).

The combination of technical developments combined with high prices enabled the new oil and gas boom in the USA. In 2014 Saudi Arabia convinced the OPEC to flood the market with oil in order to make oil production by fracking too expensive and therefore uneconomic (Rapier 2018). In spite of a 70% decrease of oil price, US shale gas and oil remained in the market and became even more competitive by further developing the technology.

2015 in Paris a worldwide agreement was achieved, that temperature change should be kept below 2 °C and measures for keeping temperature decrease below 1.5 °C should be taken (UNFCCC 2015) (see also ► “Climate Change”). In order to achieve this target, greenhouse gas emissions have to be reduced significantly within the next years (see ► “Greenhouse Gas Emissions”). Since combustion of fossil fuels as coal, gas, and oil leads to emission of CO₂, the most important greenhouse gas (IEA 2016) (see ► “Carbon Emissions”), use of fossil fuels has to be reduced (UNFCCC 2015). In order to achieve

the climate target of the Paris agreement, it is estimated that around 35% of the known oil reserves have not to be burnt (McGlade and Ekins 2015). This means that not scarcity of oil but the prevention of climate change is now the most pressing issue.

Summary

The model of peak oil was derived by Hubbert in the mid of 1950s and describes the increase and decline of production of oil under the assumption that production of oil is controlled by availability of resources, the ultimately recoverable resources of oil are known, and that production rate follows a bell-shaped curve. The oil production of some countries could be described successfully by this model, which nevertheless has some limitations as ultimately recoverable resources are depending on price of the resource and technical developments can lead to higher amounts of recoverable resources. Within the last 20 years development of unconventional fracking made production of shale oil feasible and have led to a new boom of oil production in the USA. Nevertheless greenhouse gas emissions, most important CO₂ emissions caused by burning of fossil fuels as oil, have to be reduced drastically, in order to reduce temperature increase to below 2 °C. Therefore, it is estimated that around 35% of the known oil reserves shall not be burnt and alternatives for oil have to be found independent of the timeline of peak oil.

Personhood and Sustainable Management

Definition/Description

Legal personhood – recognition as having legally enforceable rights and responsibilities – is a building block of sustainable management. It is a status enjoyed by individuals, corporations, and polities (nation states and their constituent provinces): entities that can hold, acquire/dispose of assets, engage in litigation, and act in ways that transcend an individual's life. Environmentalists and other activists are seeking to strengthen environmental sustainability and acknowledge First Nations peoples by recognizing rivers, forests, and other natural domains as legal persons under the stewardship of First Nations communities. Such a status might foster sustainable management of natural environments and strengthen the agency of communities that wish to minimize exploitation of resources by corporations and governments that prioritize immediate commercial benefit over sustainability for long-term community good. The personhood is sometimes associated with, or presented as an alternative to, a broader “rights of nature” that is not specific to a particular culture, community, or location. New understandings of personhood for sustainability are contested at a conceptual and practical level, with arguments that they are either imperative or unnecessary and that many claims regarding personhood for specific domains in the Americas, Asia, and the Pacific either lack substance or represent a “soft colonialism” contrary to the desires of First Nations.

Introduction

Sustainable management is a matter of agency: acting (or not acting) in ways that affect natural and built environments, public and private sector resource allocation and administration, and the lives of individuals (e.g., as employees, consumers, or investors) and societies (Sheehy and Farneti 2021). Agency in many pre-modern cultures encompassed both humans and cosmological entities such as gods, ghosts, demons, and spirits that might be specific to a particular such as a river, forest or mountain, governments, and

societies (Tănăsescu 2020). Managing an environment historically thus involved practices such as beseeching a deity for a bountiful harvest or placating a spirit whose anger might be expressed through a plague, storm, wildfire, or flood.

Hegemonic contemporary legal systems are founded on a different understanding of the environment and human capability. Those systems are manifestations of the Global North. They are secular, disregarding traditional cosmologies. They ascribe agency as a personhood – legally enforceable rights and responsibilities – that is enjoyed by human animals (i.e., live people), corporations (which have a legal existence independent of shareholders and unlike humans may exist in perpetuity), and polities (nation states and subsidiary entities such as provinces) (Naffine 2003; Arnold 2022).

Personhood is not enjoyed by nonhuman animals, whether domestic or wild, irrespective of sentience and sociability or by environments such as rivers and forests or by nature generally (Wise 2013; Stone 1972). Those entities might be regarded as a tradeable commodity, with, for example, cows and sheep having a legal status akin to bags of wheat: property rather entities with autonomy, liability if there is an injury, and scope for asserting rights if their interests are disregarded (Naffine 2012; Radin 1982). Environments might similarly be considered in law to be worthy of our care because of aesthetic, historical, or other value but are not recognized as persons and cannot independently appear in court if harmed through oil pollution, acid rain, manmade species loss through deforestation, or anthropogenic global warming. They are in essence acted upon rather than acting, typically subordinate to interests that may be biased toward benefits for particular stakeholders and contrary to values regarding sustainable management.

This entry identifies the salience of legal personhood for sustainable management, in particular the public/private management of natural environments. It initially outlines the nature of the personhoods which all readers have encountered, highlighting the implications for sustainable management and the emergence of law that

potentially allows corporations greater scope for resisting regulation meant to foster sustainability and social responsiveness. The entry then outlines unprecedented proposals, which are often misreported and misunderstood, for granting some form of personhood to specific domains (particular locations, especially those closely associated with First Nations). The entry deepens that outline by noting proposals regarding general “rights of nature” and duties of care on the part of public/private entities to actively address climate change on behalf of future generations.

Individuals as Legal Person

Personhood for people, more abstractly characterized as human animals, involve rights and responsibilities. Those rights involve the capability to hold property, travel, engage in employment, vote, enter intimate relationships, and enjoy considerable autonomy regarding life choices. The rights were recognized in law prior to the emergence of global human rights frameworks such as the Universal Declaration of Human Rights in the 1940s (Kateb 2014) that do not obligate all polities to ensure environmental sustainability at the national or global levels. Governments have proved reluctant to interpret human rights as requiring them to actively prevent or mitigate global warming (Bonython 2021).

The rights are correlates of responsibilities, often obfuscated by contemporary “rights talk.” As a legal person an individual might, for example, own land but be restricted by law about the use of that land, a restriction that might reflect community values regarding sustainability. Responsibilities might also involve a legally enforceable obligation not to cause injury to another person and to provide compensation if injury occurs.

Corporations as Legal Persons

Corporations are discrete legal persons with a formal status analogous to humans, that is, natural persons. As artificial persons, their personhood

involves rights and responsibilities that are articulated in a wide range of law, for example, obligations to prevent foreseeable injury in the workplace, to comply with licensing requirements, to avoid oppressive behavior that distorts markets, and to adhere to law, in particular jurisdictions regarding sustainability (Johnson 2012). They may operate on a global scale with wealth far greater than that of individual shareholders (and of many governments), useful in shaping national and global policymaking (Sheehy 2022). Corporations at law are neutral vehicles in that they have no innate norm for or against sustainability. Nevertheless, once adopting commercial norms, they become major sources of social costs (Sheehy 2004).

As artificial persons, they potentially exist in perpetuity (Stout 2014) and as a matter of self-interest or legal requirements might be persuaded to embrace a long-term perspective that fosters both sustainable management and perception of corporate legitimacy. It is important to recognize that the rights of corporations, in contrast to the rights of humans, are not inalienable. A theme running through the scholarly literature on corporate personhood is whether legislators and courts should embrace calls for giving greater rights to corporations (e.g., debate in the United States about whether corporations should have more cope for discrimination in employment and other activity on a religious basis) or whether corporations should be required by law to act in ways that benefit society at large rather than their shareholders, managers, and employees (Gear 2007; Abrams 2010). Such a requirement is pertinent given that law in many jurisdictions obliges managers to place the financial interests of shareholders ahead of employees or measures to alleviate anthropogenic heating. It may require particular corporations to abide by regulatory requirements for prudent management (e.g., bank and insurers) but broadly does not obligate directors to invest and otherwise manage for the long term, in other words emphasize sustainability rather than short-term appreciation of capital amid the innovation or risk taking valorized as creative destruction (Sheehy 2004).

Polities as Legal Persons

The personhood of polities is relevant to building sustainable management for three reasons. The first is that government agencies use natural and human resources. Their operation for example has a carbon footprint, they purchase green or other energy and consumables such as paper, and they often adhere to anti-slavery protocols. They provide benchmarks for performance in the private sector and might be regarded as exemplars of best practice in meeting targets for ethical practice, accountability (including a higher level of accountability than is required of corporations), and environmental sustainability. The second reason is that polities, through legislatures and courts, make and enforce rules about sustainable management in the private sector.

The third reason is that polities make rules about personhood. The corporation, for example, is a legal mechanism established by law in the Global North. That law is reinforced through North-centric agreements such as the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) and bilateral Free Trade Agreements that enshrine Investor-State Dispute Settlement (ISDS) mechanisms that are potentially at odds with public health and environmental protection in much of the world (Deere 2009). Law's recognition or nonrecognition of nonhuman animals, specific domains, and "nature" or "the environment" affects social expectations and corporate behavior regarding both management and sustainability. That has resulted in proposals for granting personhood to hitherto unrecognized entities such as specific geographical domains or to nature generally, alongside speculation about future recognition of artificial intelligence as legal persons (Arnold 2017; Arnold 2022; Chesterman 2020).

Personhood for Domains?

Colonization (a practice in the Americas, Africa, Asia, and other parts of the world) typically superimposed the colonizer's law on their colonial subjects or simply erased pre-colonial ontologies

regarding authority, communal property, and the place of people in a world where there was an intimate relationship between those people and domains such as forests, river systems, lakes, and mountains. In that world the particular domain was often central to the identity and lived existence of what we now characterize as First Peoples or First Nations.

Settler states such as New Zealand have recently and very inconsistently moved to recognize specific domains as what are often conceptualized as legal personhoods (Arnold 2022). The conceptualization is tied to both the domain's importance for a First Nation currently/formerly resident at that location and the minimal disruption of the particular environment through, for example, large-scale urban development, commercial afforestation, or mining. It typically involves land that it publicly owned, for example, a national park or eco preserve, rather than expropriation of private property.

The expectation is that the new person will be protected from harm, construed as development, through stewardship by First Nations stakeholders who will act on its behalf in exercising rights not to be injured or otherwise harmed. Personhood does not mean the river or other domain is responsible for injuries, for example, obliged through litigation to provide compensation to a tourist who is killed in a flood, forest fire, or landslide (Arnold 2022; Gordon 2018).

Unsurprisingly pronouncements by lower courts in India and South America about personhood for rivers and glaciers or New Zealand's establishment through legislation of particular mountains, rivers, and other domains as legal persons has attracted scholarly and popular attention (Hutchison 2014; Magallanes 2019; Ruru 2014). They have been claimed as overdue respect for First Nations as a meaningful expression of decolonization (Coombes 2020). They have also been claimed as moves toward environmental sustainability (Studley and Bleisch 2018), offsetting the weakness of existing laws in countries such as Australia and New Zealand (Bonython 2021).

As other chapters note, many of the claims misunderstand the law and what happened in

practice, with decisions in Asia and the Americas being overturned on appeal or in practice ignored by governments and businesses (Kinkaid 2019; Colón-Ríos 2015). That misunderstanding is analogous to common misrepresentation about supposed recognition in several jurisdictions of apes and other nonhuman animals as legal persons.

A more subtle concern regarding justice and sustainable management is that granting personhood for natural domains appears predicated on preservation of or return of the particular domain to a pristine state, something that is potentially at odds with the desire of First Nations and other inhabitants for development that expresses their autonomy and raises their standard of living. That conundrum may be significant in instance where people are wary of official paternalism, conscious of objectification as embodiments of pre-modern values, and seeking to raise their standard of living without having to leave a homeland. One conclusion might be that sustainability and respect for First Nations is better achieved through mechanisms other than granting personhood to trees, rocks, and water (Arnold 2022).

Personhood for Nature?

Although it is common to refer to “Mother Nature,” neither global law nor the law of individual politics regards “nature,” “Mother Earth,” or the “environment” as discrete legal persons whose status must be respected in courts and whose personhood can be defended by stewards against government and corporate abuse.
